ABSTRACT

EFFECT OF A TEMPERATURE CYCLE ON A ROTATING ELASTIC-PLASTIC SHAFT

Arslan, Eray

Ph.D., Department of Engineering Sciences

Supervisor : Prof. Dr. Ahmet N. Eraslan

January 2010, 161 pages

The stress distribution in a rotating solid shaft with temperature dependent yield stress subject to a temperature cycle is investigated. It is presumed that the shaft is in a state of generalized plane strain and obeys Tresca's yield criterion and the flow rule associated with it. By the temperature cycle it is meant that the surface temperature of the shaft is increased to a limiting value, it is held at this temperature for a while, and then slowly decreased at the same rate to the reference temperature. The isothermal shaft is rotated up to around elastic limit rotation speed and then the temperature cycle is applied to the surface of the shaft. Even in an initially purely elastic shaft, two plastic regions with different forms of the yield condition emerge simultaneously at the centre and expand into the elastic region. However, the expansion of the plastic zone ceases soon thereafter, and an unloaded region spreads into the plastic core. It is shown that the stress distribution is altered significantly by the temperature cycle, hence also leading to non-zero residual stresses at stand-still.

Keywords: Rotating shaft, temperature cycle, elastoplasticity, Tresca's criterion

Sıcaklık çevrimi uygulanan, sıcaklığa bağlı akma gerilmesine sahip malzemeden yapılmış dönen bir mildeki gerilim dağılımı incelenmiştir. Düzlem şekil değiştirme koşulu ve mil malzemesinin Tresca akma kriteri ve ilgili akma kuralına uygun olduğu varsayılmaktadır. Sıcaklık çevrimi, milin yüzey sıcaklığının bir limit değerine kadar artırılması, bu sıcaklıkta bir süre tutulması ve referans sıcaklığına aynı oranda azaltılması olarak tanımlanmıştır. İzotermal mil elastik limit dönme hızı civarına kadar döndürülmekte ve daha sonra milin dış yüzeyine sıcaklık çevrimi uygulanmaktadır. Bu durumda, başlangıçta tamamiyle elastik davranan milin merkezinde farklı akma koşullarına sahip iki plastik bölge aynı anda ortaya çıkmakta ve bu plastik bölgeler elastik bölgeye doğru genişlemektedir. Fakat bir süre sonra plastik bölgenin genişlemesi sona ermekte ve boşaltma bölgesi (unloading region) plastik merkeze doğru yayılmaktadır. Sonuç olarak mildeki gerilim dağılımı, sıcaklık çevrimiyle önemli ölçüde değişmekte ve bu da milde artık gerilmelerin (residual stresses) oluşmasına sebep olmaktadır.

Anahtar Kelimeler: Dönen mil, sıcaklık çevrimi, elastoplastisite, Tresca akma kriteri

To My Family and Prof. Werner Mack

ACKNOWLEDGMENTS

I wish to express my deepest gratitude to my advisor Prof. Dr. Ahmet N. Eraslan and Prof. Dr. Werner Mack (Vienna University of Technology, Austria) for their guidance, advice, criticism, and insight throughout this study.

I am also indebted to Prof. Dr. Udo Gamer (Vienna University of Technology, Austria) for many helpful discussions.

I owe special thanks to my advisory committee members Prof. Dr. M. Polat Saka and Prof. Dr. Tlay zbelge and examining committee members Assoc. Prof. Dr. Zafer Evis and Asst. Prof. Dr. A. Hakan Argeo for their remarkable suggestions and comments.

I would also like to thank Prof. Dr. M. Ruen Geit for his helpful advices and guidance.

I wish to extend my thanks to my roommate Baran Aydın for his useful discussions and friendship, and to Academic Writing Center of METU for their collaborative effort at the grammatical supervision of the study.

Finally, the biggest thanks go to my parents, my brothers and the most special person in my life Pelin Yksel for their endless love, patience, support and encouragement.

This study was financially supported by the State Planning Organization (DPT) Grant No: BAP-08-11-DPT2002K120510.

CHAPTER 1

INTRODUCTION

1.1 General Aspects

Rotating shafts are commonly used in most of the engineering applications to transmit power [1]–[3]. In some cases, such shafts are also exposed to nonuniform heating [4]. Hence, it is of engineering interest to an economical design of rotating transmission shafts. Due to the trend to utilize the material up to its limits, the deformation behavior of rotating shafts must carefully be analyzed in elastic and elastic-plastic ranges.

Rotating shafts that exhibit purely elastic behavior may undergo plastic deformation when subjected to an inhomogeneous temperature field. This is caused by the additional stress due to the temperature gradient and by softening of the material due to transient heating [5]. The latter effect may cause plasticization even for homogeneous heating. Indeed, rotating elastic-plastic cylindrical elements that are also subjected to thermal loads have received attention in the literature [2]–[5].

1.2 Related Literature

Investigations on this topic in the literature can be classified into three categories (See Figure 1.1). The studies that are related to the elastic and elastic-plastic behavior of rotating cylindrical elements constitute the first category. The second category includes the studies concerned with analysis of cylindrical elements which are subjected to merely thermal loading. The works that represent the solution for cylindrical ele-

ments under mechanical and thermal loads together form the third category.

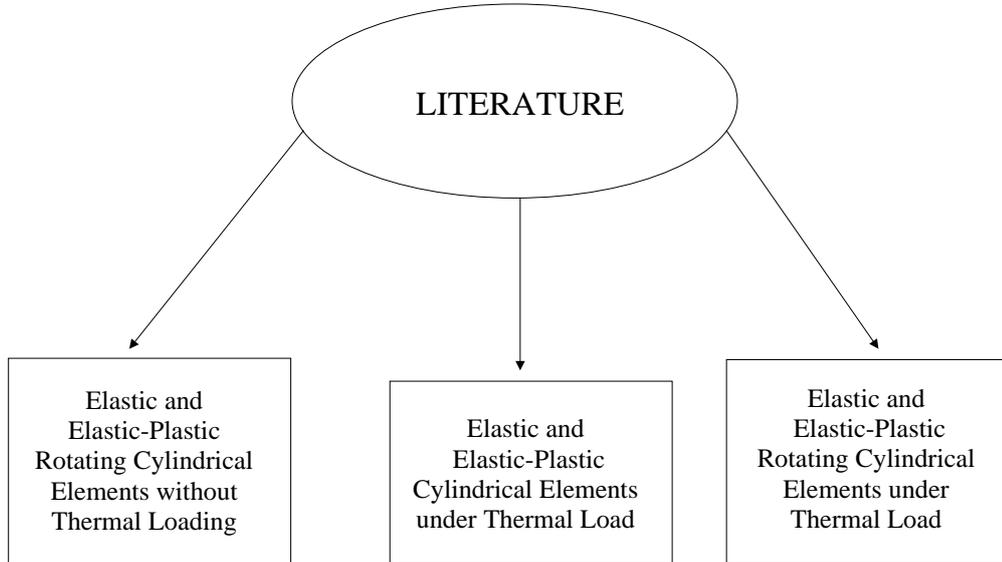

Figure 1.1: Categories of the studies in the literature

1.2.1 Rotating Cylindrical Elements without Thermal Loading

A comprehensive treatment of the rotating cylindrical elements in the elastic state of stress was presented by Timoshenko and Goodier [1]. They derived basic equations for the rotating solid and hollow disk problems, and obtained a solution for purely elastic state. In 1950, the deformation behavior beyond the elastic limits for rotating perfectly plastic cylinders was firstly treated by Nadai [6]. He considered that only one plastic region, which is an edge regime of Tresca's hexagon in principal stress space, emerges at the center of the cylinder at elastic limit rotation speed. He obtained stresses for this region. However, he did not calculate radial displacement component and did not check the kinematical continuity at the interface of the elastic and plastic regions. Hence, in the solution, it was not noticed that the compatibility requirements are not satisfied. Davis and Connelly [7] solved the rotating fully plastic strain hardening solid and hollow shaft problems in 1959. Similar to Nadai's solution, they assumed that

yielding occurs at the center of the rotating solid shaft with only one plastic region. In 1962, Hodge and Balaban [8] tried to solve the problem that was described by Nadai with more general conditions. However, plastic behavior in their work was based on the same plastic regime with Nadai. Lenard and Haddow [9] obtained instability speed for rotating solid cylinders. However, they also adopted same and wrong point of view as Nadai for plastic flow.

The common mistake that was made in the studies above was detected and corrected by Gamer and Sayir [10] in 1984. In their remarkable study, they explored that when yielding starts at the center of the rotating solid shaft in an edge regime of Tresca's hexagon in principal stress space, another plastic region in a side regime emerges simultaneously and these two regions spread together into the elastic region with the increasing rotation speed. With this solution, the necessary continuity requirement of the displacement field that fails in the Nadai's work was assured. Although all plastic and elastic regions were derived analytically in this investigation, more details concerning the latter process were presented by Gamer, Mack and Varga [11]. An analytical solution to the rotating elastic-perfectly plastic solid shaft with axially unconstrained ends was derived by Mack [12] in 1991. On the other hand, the residual stresses in a rotating elastic-perfectly plastic solid shaft with fixed ends, which means that the long tube is constrained at both ends in the axial direction with rigid plates, were obtained by Lindner and Mack in another work [13].

Gamer and Lance [14] obtained stresses and radial displacement in rotating linearly hardening hollow shaft with fixed ends in 1983. Mack [15] treated the problem of rotating elastoplastic hollow shaft with free ends in 1991. In his another study [16], he investigated the unloading and the secondary flow in a rotating elastic-plastic hollow cylinder.

Some studies related with the rotating strain hardening disks, where the plane stress state is assumed inversely to the shafts, are given below. Guven [17] obtained an exact solution for the rotating elastoplastic hyperbolic disk that is mounted on a rigid solid shaft. Eraslan and Orcan [18] solved the same problem analytically for the exponential concave profiles of a solid disk. Eraslan and Argeso [19] developed a computational model for rotating nonlinearly hardening solid disk of variable thickness. Eraslan [20]

then obtained an analytical solution to linearly hardening and a numerical solution to nonlinearly hardening rotating disks with an elliptical thickness profile.

The exact solutions for the elastic-plastic deformations of a rotating linearly strain hardening solid shaft were firstly obtained by Eraslan [21] in 2003. One year later, Eraslan [22] developed a computational model for rotating elastoplastic nonlinearly strain hardening shafts. Another computational study was performed for estimating residual stresses and secondary plastic flow limits in rotating nonlinearly hardening shafts by Eraslan and Mack [23] in 2005.

In 1999, Horgan and Chan [24] studied the deformations of a rotating linearly elastic disk and shaft made of Functionally Graded Material (FGM). FGMs are nonhomogeneous but isotropic materials. In their composition, physical properties vary throughout the material. In Horgan and Chan's analytical study, modulus of elasticity varies with the radial coordinate and this variation depends on a power law. However, the modulus of elasticity becomes zero at the center based on nonlinear power function of the radial coordinate. This result is physically unrealistic. Hence, Eraslan and Akis [25] used exponential and parabolic functions of the radial coordinate describing the modulus of elasticity which then becomes non-zero and they obtained a closed form solution for the rotating functionally graded solid shaft and disk at the elastic range and the onset of the yield. The same authors developed an analytical model for functionally graded hollow shaft with fixed and free ends in [26]. In 2006, the problem of rotating functionally graded perfectly plastic hollow shafts was solved by the same authors [27]. Then, the perfectly plastic FGM hollow shafts for free ends was solved by Eraslan and Arslan [28] and for fixed ends by Akis and Eraslan [29] in 2007.

1.2.2 Cylindrical Elements under Thermal Load

Whenever temperature difference exists between any sections of a cylindrical element, stresses and displacement are set in the material whose boundaries are constrained or not. The magnitudes of the response variables depend on either the magnitude of temperature difference if it is in the steady-state or temperature variation with time if it is in unsteady-state [30]. On the other hand, different combinations of the heat treatment on different geometries cause interesting and unpredictable stress state

combinations. Therefore, heat treatment of the metals has been a popular subject for the most investigators. The studies, which are directly related to the current one and may draw the attention of interested readers, are introduced below.

One of the oldest solutions to the thermal stress problem was presented by Dahl [30] in 1924. Dahl investigated stress distribution in thick and thin walled hollow cylinders, which is subjected to steady-state temperature distribution. Another old study in heat-treated elastic and perfectly plastic shafts was presented by Weiner and Huddleston [31] in 1959. Boley and Weiner [4] also presented expressions of the stresses and displacement in an elastic disk and a shaft, which are subjected to steady-state temperature gradient. Timoshenko and Goodier [1] and Johnson and Mellor [32] also reviewed the elastic solution of the problem. In 1960, Landau and Zwicky [33] solved the problem of elastic-perfectly plastic solid shaft with transient temperature distribution under the condition of temperature-dependent yield stress. In 1968, Mendelson [34] formulated a predeformed elastic region, which emerges after unloading and includes permanent plastic strains, for a solid shaft with radial temperature distribution.

In 1974, Chu [35] obtained a solution for a thermoelastoplastic strain hardening hollow shaft subjected to transient thermal load. Perzyna and Sawczuk [36] extensively reviewed the thermally induced deformation of the elastoplastic cylindrical elements. Then, Ishikawa [37] obtained an elastic-plastic solution for a solid shaft subjected to rapid surface heating and cooling.

In 1988, Mack and Gamer [38] investigated the thermal stresses that remain in the non-rotating elastic-plastic cylindrical elements after the unloading. In their study, transient heating was applied to the material and the derivation of predeformed elastic region was presented. They suggested that the exact unloading occurs all of a sudden in the deformed part of the material. They then compared the results of the exact and approximated unloading and concluded that the error of approximated sudden unloading is negligibly small. In a later work, Jahanian and Sabbaghian [39] obtained the residual stresses in an elastoplastic linearly hardening hollow shaft subjected to rapid cooling of the surface.

Moreover, the centrally heat-generating solid or composite shafts problem whose elastic solutions were obtained by Valentin and Carey [40], Citakoglu [41] and Citakoglu

and Eren [42] has a special importance for the nuclear investigations. Analytical solutions of the elastic-perfectly plastic deformation of a centrally and slowly heated solid shaft with fixed ends by Orcan and Gamer [43], and with free ends by Orcan [44]. Gulgec and Orcan investigated the elastic-plastic deformation of a heat generating hollow shaft with fixed ends in [45] and with free ends in [46] under the assumption of a linear dependence of the yield stress on the temperature. In a following study, thermal stresses for the same problem but in an elastic-perfectly plastic hollow shaft with temperature dependent mechanical and thermal properties were obtained by Orcan and Eraslan [47]. Thereafter, Eraslan [48] obtained an exact solution to thermally induced elastic-plastic stress distributions in nonuniform heat generating composite tubes with axially fixed ends in 2003.

A closed form solution of a linearly hardening solid shaft subjected to nonuniform steady-state thermal load and convective boundary condition were obtained by Eraslan and Orcan [49]. In another study, Eraslan and Argeso [50] developed a computational model to estimate elastic-plastic stress states considering temperature-dependent physical properties for nonlinearly hardening cylindrical materials. This study was detailed in the same authors' another work [51] and the problem was solved with different assumptions.

1.2.3 Rotating Cylindrical Elements under Thermal Load

In one of the oldest studies that presents a solution for elastic rotating solid disk with a steady-state temperature gradient was obtained by Mendelson [34] in 1968. In a later work, Alujevic et al. [52] discussed the onset of yielding of a rotating hyperbolic annular disk for a given steady-state temperature distribution. In another study, Alujevic et al. [53] obtained numerical results for the previous work [52]. In 1998, Parmaksizoglu and Guven [54] studied the combined influence of nonuniform steady-state heating and rotation in a linearly hardening disk which is mounted on a rigid shaft in the fully plastic state.

Tarn [55] obtained an exact solution for the elastic functionally graded anisotropic hollow and solid circular cylinders, which are subjected to the thermal loads and rotation. An elastic-plastic analysis of a rotating shrink fit was obtained by Mack and Plöchl in

[56] and Mack et al. in [57]. In 2003, Eraslan and Akis [58] analyzed the elastic-plastic stress distribution in a rotating linearly and nonlinearly hardening hollow thin disk which is mounted on a rigid shaft subjected to a steady-state temperature gradient.

In a later work, Eraslan, Arslan and Mack [59] obtained an exact solution for the distribution of stresses and displacement in a rotating linearly hardening elastic-plastic hollow shaft with free ends subject to a positive steady-state temperature gradient. In a recent study, Arslan, Mack and Eraslan [60] completed the investigations on such types of hollow shafts by considering a heated inner surface. Analytical solution for the distribution of the stresses and radial displacement in a linearly hardening elastic-plastic hollow shaft subjected to the increasing angular speed and a negative radial temperature gradient was presented.

1.3 Scope of the Present Work

The literature review above indicates that an analogous investigation for a rotating solid shaft which is subjected to unsteady thermal load has not been conducted. Therefore, in the present study, a rotating solid cylinder with free surface is subjected to a temperature cycle. The temperature cycle is structured as follows: The surface temperature of the shaft is increased slowly and linearly with time up to a certain maximum temperature value. Then, it remains constant at this temperature for some time. Finally, it is decreased linearly to its reference temperature with time. In the problem, the elastic shaft is initially rotated up to a certain rotation speed, which is less than the elastic limit rotation speed for the isothermal shaft. Then the speed is held constant and the heating cycle described above is applied. It is assumed that the shaft is not axially constrained. Under presupposing circular symmetry and generalized plane strain, the problem is amenable to an analytical treatment. The material is presumed to be elastic-plastic and to obey Tresca's yield criterion and its associated flow rule. Furthermore, the yield stress decreases linearly with temperature. The treatment is restricted to small deformations. Then, a certain type of elastoplastic behavior is found to be typical. That is, at the axis of the shaft two plastic regions emerge, simultaneously. The image points of the inner plastic region lie on an edge and the ones of the other plastic region lie on an adjacent side of the Tresca's hexagon as

in other cylinder problems [10]. In time, these two plastic regions move into the outer zone of the shaft. After a certain time, the plastic zone does not expand any more, and elastic unloading occurs at the plastic-elastic border before the fully plastic state is obtained. Thereafter, the predeformed elastic region spreads rapidly into the plastic zone. The distribution of the stresses, radial displacement and plastic strains are calculated and displayed for elastic region, two plastic regions, and predeformed elastic region at different times. The residual stresses after stand-still are also calculated and presented.

CHAPTER 2

THEORY

2.1 The Stress-Strain Relation

The most common and simplest experiment, as well as the most important, is the tensile test to determine the stress-strain relationship of a material [34]. In this experiment, increasing tensile load P is applied to the specimen of the material. Then the nominal stress which is defined by

$$\sigma_n = \frac{P}{A_0}, \quad (2.1)$$

where A_0 is the original cross sectional area of the specimen, is calculated. Measuring the length L of the specimen, the engineering strain given by

$$\epsilon = \frac{L - L_0}{L_0}, \quad (2.2)$$

in which L_0 is the original length, is determined and the stress-strain diagram is drawn. A typical stress-strain diagram of a ductile material is shown in Figure 2.1. In this figure, the linear portion of the curve extends up to proportional limit σ_p . Until this limit, the slope of the line gives modulus of elasticity E and Hooke's law is valid there:

$$\sigma_n = E\epsilon. \quad (2.3)$$

Between proportional limit and yield stress, σ_y , the material still behaves elastic although stress-strain relationship is not constant. Additionally, difference between proportional limit and yield stress is very small for most ductile materials. Hence, it is considered that they coincide with each other.

For $\sigma_y < \sigma < \sigma_u$, where σ_u is the ultimate stress, the material behaves plastically. In this region, the strain increases at a greater rate as load is increased beyond the yield stress. However, the specimen will not deform further unless the load is increased. Hence, this region is called strain hardening region. For the stresses larger than ultimate stress, necking region, which is not recommended amount of loading for any engineering point of view, governs on the material. This region eventuates with the becoming unstable neck and the rupturing specimen when stress becomes equal to failure stress σ_f [61].

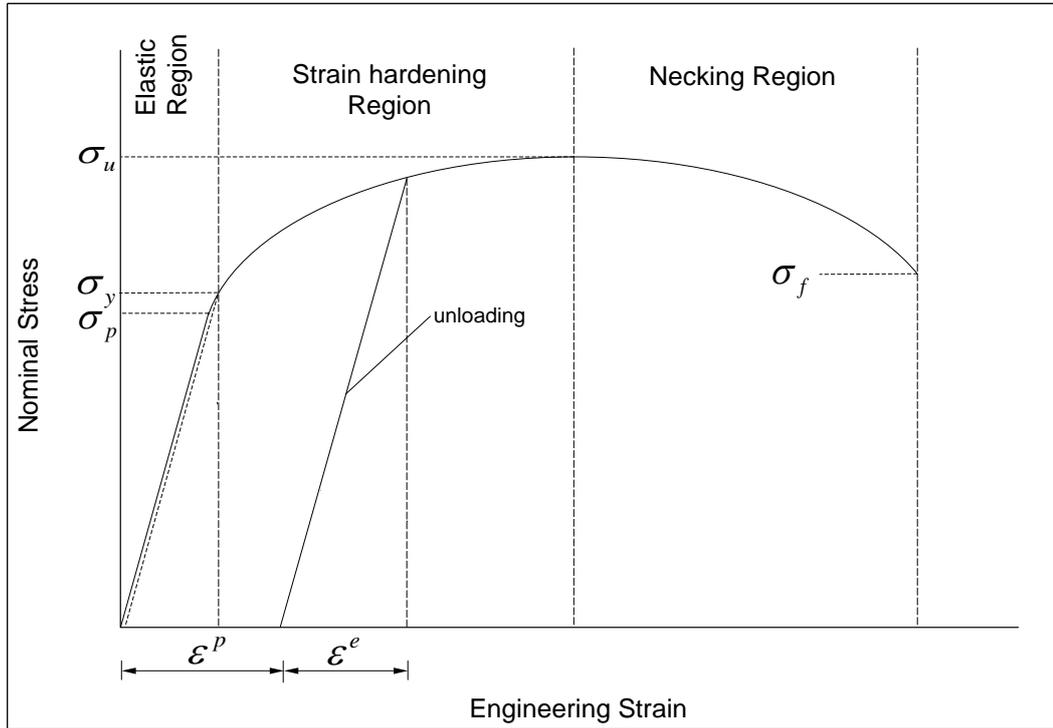

Figure 2.1: Stress-strain Diagram

In the elastic region, when unloading starts, material returns to its original shape. However, if the load is removed at any point in strain hardening region, unloading will take place along a line which is parallel to the elastic line as shown in Figure 2.1. As load is completely removed, elastic strain, i.e., ϵ^e , is recovered but the permanent plastic strain, i.e., ϵ^p , remains. Hence the total strain can be considered as summation of these two strain components [34]

$$\epsilon = \epsilon^e + \epsilon^p. \quad (2.4)$$

2.2 Criteria of Yielding

A law defining the limit of elasticity under any possible combination of stresses is called a criterion of yielding [62]. As seen in Figure 2.1, for the stresses being larger than σ_y , behavior of the material is described by using any yielding criterion. Plastic yielding may depend on the magnitude of the three principal applied stresses, but not on their directions, since the isotropic case is assumed. Numerous criteria have been proposed for the yielding of solids, i.e. Maximum stress theory, maximum strain theory, Von Mises' criterion, Tresca's criterion, etc. Among these, Von Mises' yield criterion and Tresca's yield criterion are reasonably simple mathematically and accurate enough to be highly useful for the initial yield of isotropic materials.

2.2.1 Von Mises' Yield Criterion

The criterion, which is also known as distortion energy theory, is attributed to Von Mises [63]. In this theory, failure by yielding occurs at any coordinate of the material when the distortion energy per unit volume in a state of combined stress becomes equal to that associated with yielding in a simple tension test [3]. In other words, when the second deviatoric stress invariant reaches a specified value, yielding emerges. The principal stress, for $\sigma_1 > \sigma_2 > \sigma_3$, form of the Von Mises' yield criterion in simple tension is

$$(\sigma_1 - \sigma_2)^2 + (\sigma_2 - \sigma_3)^2 + (\sigma_1 - \sigma_3)^2 = 2\sigma_y^2, \quad (2.5)$$

where σ_y denotes the yield stress. As seen in Eq. (2.5), only the differences of the principal stresses involved. Therefore, yielding condition is not influenced by any additional amount to the each stress [3].

Von Mises' yield criterion finds considerable experimental support in situations involving ductile materials. Consequently, it is in common use in design [3].

2.2.2 Tresca's Yield Criterion

Tresca's yield criterion which is also called as maximum shear theory was firstly suggested by Tresca [64]. In this work, he concludes that yielding occurs when the

maximum shear stress in the material equals maximum shear stress at yielding in a simple tension test. In other words, the maximum shear stress is equal to half of difference between maximum and minimum principal stresses. Hence, for the prescribed principal stresses, $\sigma_1 > \sigma_2 > \sigma_3$, Tresca's yield condition is

$$\pm \frac{1}{2}(\sigma_1 - \sigma_3) = \tau_{\max}. \quad (2.6)$$

In the simple tension, the maximum shear stress at yielding point is half of the yield stress, $\sigma_y/2$. Therefore, Tresca's criterion claims that yielding emerges when any of the following conditions is reached [34]

$$\sigma_1 - \sigma_3 = \pm \sigma_y, \quad (2.7)$$

$$\sigma_1 - \sigma_2 = \pm \sigma_y, \quad (2.8)$$

$$\sigma_2 - \sigma_3 = \pm \sigma_y. \quad (2.9)$$

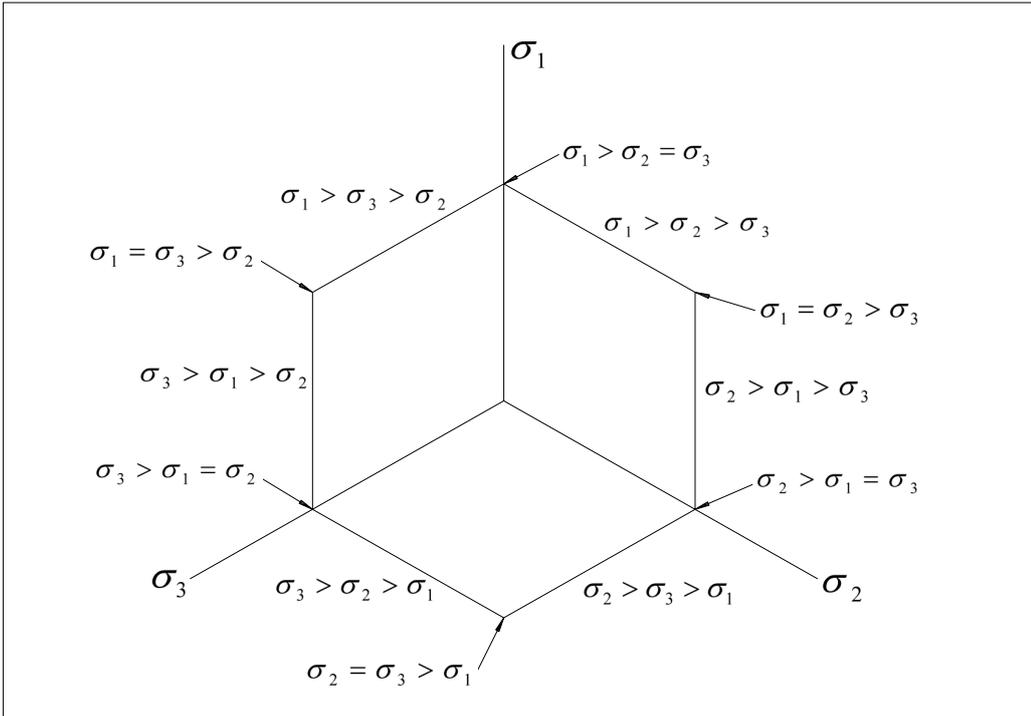

Figure 2.2: Tresca's hexagon with yielding conditions on three-dimensional principal stress space

In Figure 2.2, Tresca's yield criterion is presented as a regular hexagon in the deviatoric plane of the three-dimensional principal stress space [15]. The boundary of the

hexagon marks the onset of yielding and the points outside of the hexagon represents a yielded state [3]. On this hexagon, each side and edge represent different type of yielding conditions. At the edge regimes of the Tresca's hexagon, two of principal stresses are equal to each other. On the other hand, there exists an inequality between principal stresses on the side regimes. For example, for the principal stresses space $\sigma_1 > \sigma_3 > \sigma_2$ (see the side regime in Figure 2.2), Tresca yielding condition reads $\sigma_1 - \sigma_2 = \sigma_y$. For the principal stress space $\sigma_1 = \sigma_3 > \sigma_2$ (edge regime in Tresca's hexagon), yielding conditions become $\sigma_1 - \sigma_2 = \sigma_y$ and $\sigma_3 - \sigma_2 = \sigma_y$. Similarly, yielding conditions of remaining side and edge regimes of the Tresca's hexagon may be obtained.

Tresca's yield criterion has a good agreement with experimental results for ductile materials and the theory offers an additional advantage in its ease of applications [3]. The criterion is mostly chosen for the theoretical treatment of the yielding problem since it generally makes a closed form solution possible.

2.3 Flow Rule Associated with Yield Criteria

The flow rule is the necessary kinematic assumption for the plastic deformation. It gives the ratio of the plastic strain increment tensor $d\epsilon_{ij}^p$, and it also defines the direction of the plastic strain increment vector in the strain space [65]. To obtain the plastic flow equations, the first approach to plastic strain-stress was suggested by Saint-Venant [66]. He proposed that the principal axes of the strain increment, but not total strain, coincides with the axes of the principal stress. A general relationship between the ratios of the components of strain increment and the stress was firstly suggested by Levy [67] and then independently by Von Mises [63]. Hence, equations given below are called Levy-Mises equations.

$$\frac{d\epsilon_{xx}}{S_{xx}} = \frac{d\epsilon_{yy}}{S_{yy}} = \frac{d\epsilon_{zz}}{S_{zz}} = \frac{d\epsilon_{xy}}{S_{xy}} = \frac{d\epsilon_{xz}}{S_{xz}} = \frac{d\epsilon_{yz}}{S_{yz}} = d\lambda, \quad (2.10)$$

or more compactly,

$$d\epsilon_{ij} = S_{ij}d\lambda, \quad (2.11)$$

where S_{ij} ($i, j : x, y, z$) is the stress deviator tensor and $d\lambda$ is a positive scalar factor of proportionality and non-zero only when plastic deformation occurs [65]. However, these equations are only for the rigid materials in which elastic strains are zero because total strain increments equalized to plastic strain increments. Hence, the extension of the Levy-Mises equation to allow for the elastic strains was carried out by Prandtl [68]. Then, Reuss [69] suggested the plastic strain increments $d\epsilon_{ij}^p$ related to the deviatoric stress components by the Prandtl-Reuss equations

$$\frac{d\epsilon_{xx}^p}{S_{xx}} = \frac{d\epsilon_{yy}^p}{S_{yy}} = \frac{d\epsilon_{zz}^p}{S_{zz}} = \frac{d\epsilon_{xy}^p}{S_{xy}} = \frac{d\epsilon_{xz}^p}{S_{xz}} = \frac{d\epsilon_{yz}^p}{S_{yz}} = d\lambda, \quad (2.12)$$

or

$$d\epsilon_{ij}^p = S_{ij}d\lambda. \quad (2.13)$$

These equations prove that the principal axes of stress and plastic strain-increment coincide for isotropic materials [62].

To express a general stress-strain relation, a loading function $f(\sigma_{ij})$ is assumed. According to this assumption, plastic deformation forms only for $f(\sigma_{ij}) = k$ and $df > 0$, where k depends on the stress state and the strain history. Additionally, the increase in the plastic strain is a linear function of the increase in stress.

The condition that $df = 0$ is satisfied by assuming that

$$d\epsilon_{ij}^p = G_{ij}df, \quad (2.14)$$

in which G_{ij} is a symmetric tensor which are supposed to be functions of the stress components and possibly of the previous strain history [62]. For the case of zero plastic volume change, assumption of $G_{ij} = 0$ leads to

$$G_{ij} = h \frac{\partial g}{\partial \sigma_{ij}}, \quad (2.15)$$

where g and h are general function of stress and strain flow [62]. Substituting Eq. (2.15) into Eq. (2.14) gives

$$d\epsilon_{ij}^p = h \frac{\partial g}{\partial \sigma_{ij}} df. \quad (2.16)$$

This equation is firstly obtained by Melan [70]. When the yield function and the plastic potential function coincide, $f = g$, following relation is obtained (see Hill [62])

$$d\epsilon_{ij}^p = \frac{\partial f}{\partial \sigma_{ij}} d\lambda. \quad (2.17)$$

These relations show that plastic flow develops along the normal to the flow surface $\partial f / \partial \sigma_{ij}$. Eq. (2.17) is known as associated flow rule with the yield condition since the plastic flow is associated with the yield criterion. Furthermore, plastic flow can be expressed in terms of several yield functions as following

$$d\epsilon_{ij}^p = \frac{\partial f_1}{\partial \sigma_{ij}} d\lambda_1 + \frac{\partial f_2}{\partial \sigma_{ij}} d\lambda_2 + \dots + \frac{\partial f_n}{\partial \sigma_{ij}} d\lambda_n. \quad (2.18)$$

2.3.1 Flow Rule Associated with Tresca Yield Function

If the Tresca yield function is taken as the plastic potential, the flow rule associated with it can be expressed in the light of Section 2.3. By supposing that the ordering in magnitude of the principal stresses is $\sigma_1 > \sigma_2 > \sigma_3$ (a side region of Tresca's hexagon in principal stress space as seen in Figure 2.2), the corresponding yield function takes the form

$$f = F(\sigma_{ij}) - 2k = \sigma_1 - \sigma_3 - 2k = 0, \quad (2.19)$$

where k is the yield value [65]. By substituting the yield function into the associated flow rule Eq. (2.17), the principal plastic strain increments, $d\epsilon_1^p, d\epsilon_2^p, d\epsilon_3^p$, are obtained as follows:

$$d\epsilon_1^p = \frac{\partial f}{\partial \sigma_1} d\lambda = d\lambda, \quad (2.20)$$

$$d\epsilon_2^p = \frac{\partial f}{\partial \sigma_2} d\lambda = 0, \quad (2.21)$$

$$d\epsilon_3^p = \frac{\partial f}{\partial \sigma_3} d\lambda = -d\lambda. \quad (2.22)$$

Similar results can be obtained for the other five possible combinations in algebraic orders of magnitude of the principal stresses. These are on the side regime of Tresca's hexagon in principal space. Furthermore, the increments of plastic strains are parallel to each other and perpendicular to the side of the hexagon (see Chen and Han [65]).

On the other hand, an example to edge regime of Tresca's hexagon (see Figure 2.2) may be $\sigma_1 > \sigma_2 = \sigma_3$ in principal stress space. In this more involved case, shear slip may occur along either of two possible maximum shear planes which are [65]

i) $\sigma_{\max} = \sigma_1, \sigma_{\min} = \sigma_2$. Therefore

$$d\epsilon_1^p = d\lambda_1, \quad (2.23)$$

$$d\epsilon_2^p = -d\lambda_1, \quad (2.24)$$

$$d\epsilon_3^p = 0, \quad (2.25)$$

where $d\lambda_1 \geq 0$.

ii) $\sigma_{\max} = \sigma_1, \sigma_{\min} = \sigma_3$. Therefore

$$d\epsilon_1^p = d\lambda_2, \quad (2.26)$$

$$d\epsilon_2^p = 0, \quad (2.27)$$

$$d\epsilon_3^p = -d\lambda_2, \quad (2.28)$$

where for $d\lambda_2 \geq 0$. In this case, it is assumed that the resulting plastic strain increment vector is a linear combination of the two increments (see Eq. (2.18))

$$d\epsilon_1^p = d\lambda_1 + d\lambda_2, \quad (2.29)$$

$$d\epsilon_2^p = -d\lambda_1, \quad (2.30)$$

$$d\epsilon_3^p = -d\lambda_2. \quad (2.31)$$

Similarly, for remaining five edges of the Tresca's hexagon, the associated flow rules with Tresca's yield criterion may be obtained.

CHAPTER 3

STATEMENT OF THE PROBLEM AND TEMPERATURE FIELD

3.1 Statement of the Problem

Consider a rotating solid shaft cross section of which is shown in Figure 3.1. The shaft is subjected to temperature cycle. In formulation, cylindrical polar coordinates, i.e. r is radial, θ is circumferential, and z is axial directions, are considered. Notation of Timoshenko and Goodier [1] is followed. Hence, σ_i and ϵ_i denote a normal stress and a normal strain component ($i : r, \theta, z$), respectively, u is the radial component of the displacement vector, ρ is the mass density of the shaft material, and ω is constant angular speed of rotation. The subject of the investigation is a rotating elastic-perfectly plastic solid shaft with outer radius b with stress free cylindrical surface (see Figure 3.1) [12]

$$r = b : \quad \sigma_r = 0. \quad (3.1)$$

Another mechanical boundary condition is that axial force F_z on any cross-section vanishes since the ends of the shaft are free [12]

$$F_z = 2\pi \int_0^b \sigma_z r dr = 0. \quad (3.2)$$

For completeness, it is stated that the radial displacement component has to comply with the condition (see [12])

$$u(0) = 0, \quad (3.3)$$

since shaft is solid. A state of generalized plane strain, i. e.

$$\epsilon_z = \epsilon_0 = \text{Constant}, \quad (3.4)$$

where the axial strain ϵ_0 depends on the angular speed and the temperature field, is considered. Additionally, infinitesimal deformations are presumed. Since end effects are ignored and cylindrical symmetry is presumed, the principal directions of stress and strain are the radial, circumferential and axial directions [11]. As already mentioned, the material is assumed to obey Tresca's yield criterion and the associated flow rule with it [32], [65]. For a linear temperature dependence the yield stress, σ_{th} , reads

$$\sigma_{th} = \sigma_0 (1 - \beta T), \quad (3.5)$$

where σ_0 denotes the uniaxial yield limit at reference temperature and β the temperature dependence parameter of the material [45], [56]. T , which will be examined in the Section 3.2, means the difference of absolute and reference temperatures.

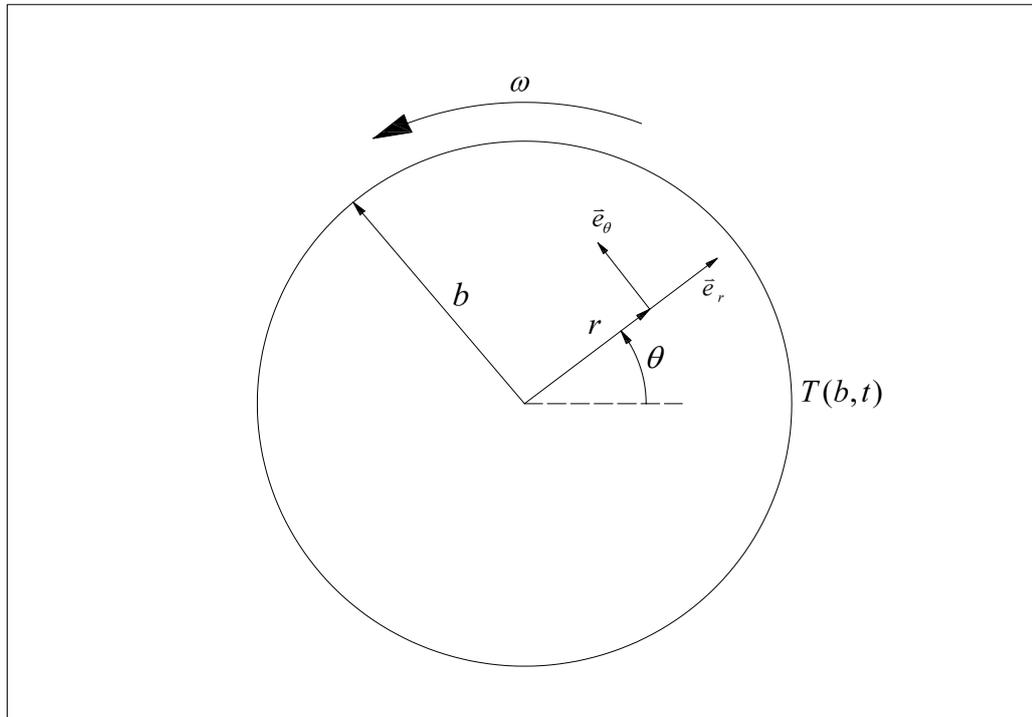

Figure 3.1: Sketch of the rotating solid shaft subjected to temperature cycle

3.2 Temperature Field

Temperature cycle that is applied to outer surface of the shaft is sketched in Figure 3.2. As seen in the figure, the temperature at the surface of the shaft is increased

linearly and slowly up to maximum temperature value T_m in time t_t . Then, it is held constant throughout $t = t_c$. Finally, it is decreased linearly at the same rate to the reference temperature until $t = 2t_t + t_c$. For $t > 2t_t + t_c$, surface temperature remains at the reference temperature value.

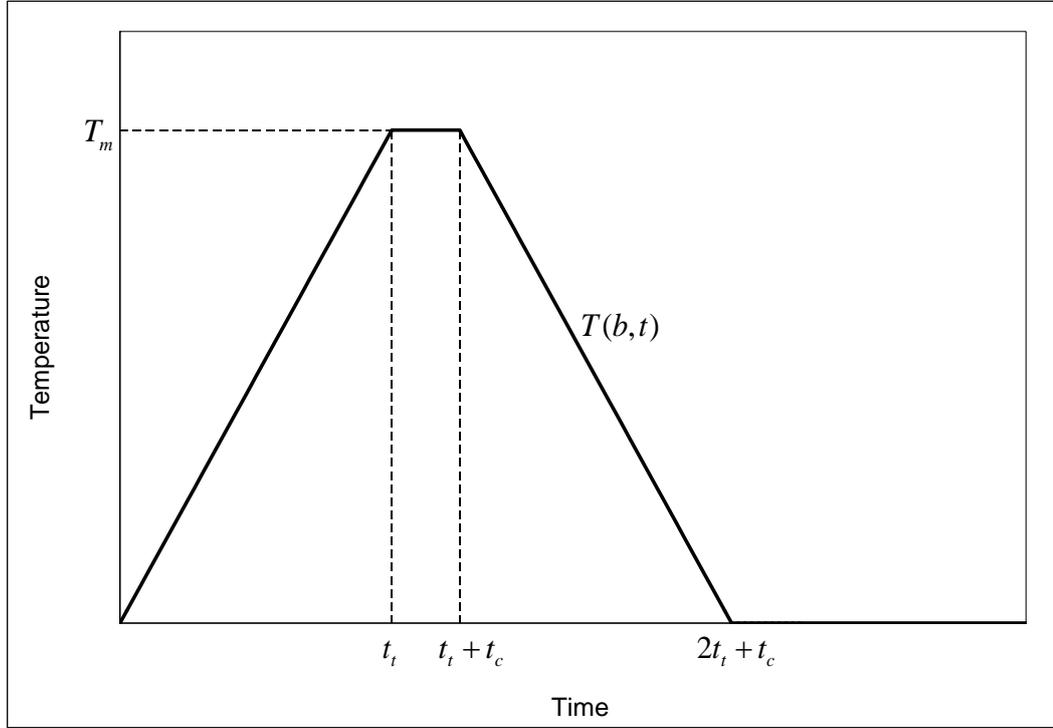

Figure 3.2: Prescribed surface temperature of the shaft

To model this temperature cycle, the surface temperature of the shaft is prescribed as a sectionally linear function of time [56]. Thus, the heat conduction problem is described by the following differential equation:

$$\frac{\kappa}{r} \frac{\partial}{\partial r} \left[r \frac{\partial T(r,t)}{\partial r} \right] = \frac{\partial T(r,t)}{\partial t}, \quad (3.6)$$

in which κ denotes the thermal diffusivity, subject to the initial condition

$$T(r,0) = 0 \quad \text{for} \quad 0 \leq r \leq b, \quad (3.7)$$

and to the boundary condition (see Figure 3.2)

$$T(b, t) = \begin{cases} (T_m/t_t) t & \text{for } 0 < t \leq t_t \\ T_m & \text{for } t_t < t \leq t_t + t_c \\ T_m - (T_m/t_t)(t - t_t - t_c) & \text{for } t_t + t_c < t \leq 2t_t + t_c \\ 0 & \text{for } t > 2t_t + t_c \end{cases} . \quad (3.8)$$

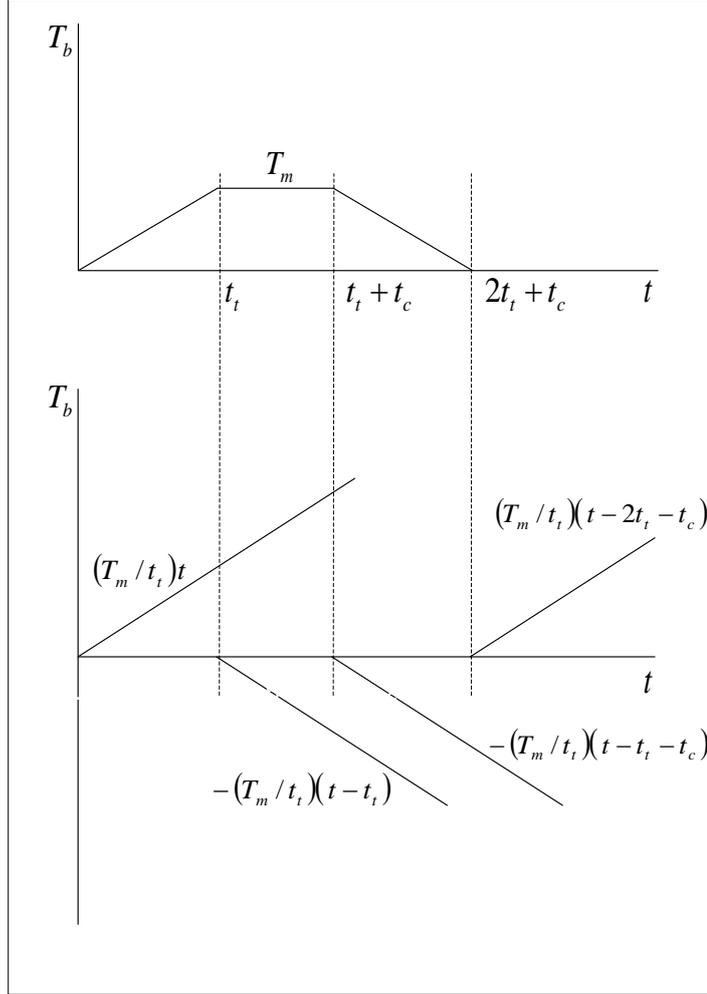

Figure 3.3: Description of surface temperature with linear function

Solution of the heat conduction equation has been obtained in [71] for zero initial temperature (Eq. (3.7)) and the surface temperature of $T(b, t) = (T_m/t_t) t$ as following

$$\bar{T}(r, t) = \frac{T_m}{t_t} \left[\left(t - \frac{b^2 - r^2}{4\kappa} \right) + \frac{2}{\kappa b} \sum_{n=1}^{\infty} e^{-\kappa\gamma_n^2 t} \frac{J_0(r\gamma_n)}{\gamma_n^3 J_1(b\gamma_n)} \right], \quad (3.9)$$

where J_0 and J_1 indicate Bessel functions of the first kind of order zero and one,

respectively, and the γ_n are the positive roots of

$$J_0(b\gamma) = 0. \quad (3.10)$$

This solution is valid for time interval $0 < t \leq t_t$ since boundary condition in this interval is $T(b, t) = (T_m/t_t)t$. In order to find the solution for the range of $t > t_t$, different linear functions are defined as shown in the Figure 3.3. By superposition of these linear functions, the boundary condition for each time interval in Eq. (3.8) can be obtained.

Hence, the solution of heat conduction problem (3.9) can be adapted for all time intervals as

$$T(r, t) = \begin{cases} \bar{T}(r, t) & \text{for } 0 < t \leq t_t \\ \bar{T}(r, t) - \bar{T}(r, t - t_t) & \text{for } t_t < t \leq t_t + t_c \\ \bar{T}(r, t) - \bar{T}(r, t - t_t) - \bar{T}(r, t - t_t - t_c) & \text{for } t_t + t_c < t \leq 2t_t + t_c \\ \bar{T}(r, t) - \bar{T}(r, t - t_t) - \bar{T}(r, t - t_t - t_c) \\ \quad + \bar{T}(r, t - 2t_t - t_c) & \text{for } t > 2t_t + t_c \end{cases} \quad (3.11)$$

CHAPTER 4

BASIC EQUATIONS AND ANALYTICAL SOLUTIONS OF ELASTIC AND PLASTIC REGIONS

4.1 Basic Equations

Equation of motion that is derived by using Newton's second law, is the primary equation that is used for the mathematical derivation of elastic and plastic regions. General form of equation of motion in radial direction is as derived in [1]

$$\frac{\partial \sigma_r}{\partial r} + \frac{1}{r} \frac{\partial \tau_{r\theta}}{\partial \theta} + \frac{\sigma_r - \sigma_\theta}{r} + R = 0, \quad (4.1)$$

where $\tau_{r\theta}$ is shear stress and R is component of body force. In this problem, the shear stress $\tau_{r\theta}$ vanishes because of the symmetry [1]. Hence, terms of $\partial \tau_{r\theta} / \partial \theta$ drops in Eq. (4.1). Additionally, the body force R is described with neglecting weight of the shaft as

$$R = \rho \omega^2 r + \rho \frac{\partial^2 u}{\partial t^2}, \quad (4.2)$$

where ρ is mass per unit volume of the material and ω is constant angular rotation speed of the shaft [1], [4]. In this equation, the first term, $\rho \omega^2 r$, is an inertia force that occurs because of rotation [1]. The second term, i.e. $\rho (\partial^2 u / \partial t^2)$, is another inertia term that is formed due to thermally induced wave phenomena. In case of sudden temperature change in a material, such as quenching of a hot shaft, this term has a significant effect on the body force. On the other hand, if the temperature is altered slowly in time, this inertia force does not influence the material [4]. Hence, the second term in the body force drops in this study, $\rho \frac{\partial^2 u}{\partial t^2} = 0$, since the temperature cycle (in Figure 3.2) is applied to the surface of the shaft slowly. Therefore, for constant angular speed, in the absence of thermally induced wave phenomena, neglecting weight

of the shaft and in case of cylindrical symmetry, the equation of motion for the radial direction in Eq. (4.1) takes the form

$$(r\sigma_r)' - \sigma_\theta = -\rho\omega^2 r^2. \quad (4.3)$$

In this equation, a prime denotes differentiation with respect to r as radial and circumferential stresses are independent of circumferential direction θ .

Since the treatment is restricted to small deformations, radial and circumferential strain components are described with the following geometric relations in case of cylindrical symmetry as

$$\epsilon_r = u', \quad \epsilon_\theta = \frac{u}{r}. \quad (4.4)$$

Another basic relation is Generalized Hooke's law [4], which follows as

$$\epsilon_r = \frac{1}{2(1+\nu)G} [\sigma_r - \nu(\sigma_\theta + \sigma_z)] + \epsilon_r^p + \alpha T, \quad (4.5a)$$

$$\epsilon_\theta = \frac{1}{2(1+\nu)G} [\sigma_\theta - \nu(\sigma_r + \sigma_z)] + \epsilon_\theta^p + \alpha T, \quad (4.5b)$$

$$\epsilon_z = \epsilon_0 = \frac{1}{2(1+\nu)G} [\sigma_z - \nu(\sigma_r + \sigma_\theta)] + \epsilon_z^p + \alpha T, \quad (4.5c)$$

where ν denotes Poisson's ratio, G is modulus of rigidity, ϵ_i^p are plastic strain components and α is the coefficient of thermal expansion in material [56], [59]. It is presumed that the strains are additively composed of elastic, plastic and thermal parts in these equations.

4.2 Elastic Region

In the elastic deformation, Eqs. (4.5a–4.5c) are recovered by setting $\epsilon_i^p = 0$. Axial stress is determined in terms of radial and circumferential stresses from Hooke's law (4.5c) in a state of generalized plane strain (Eq. (3.4)) as

$$\sigma_z = \nu(\sigma_r + \sigma_\theta) + 2G(1+\nu)[\epsilon_0 - \alpha T(r, t)]. \quad (4.6)$$

On the one hand, by making use of geometric relations (4.4) and Hooke's law in radial and circumferential directions (4.5a) and (4.5b), following stress components are derived in terms of radial displacement and its derivative with help of Eq. (4.6)

$$\sigma_r = \frac{2G}{r(1-2\nu)} [\nu u + r(1-\nu)u' + r\nu\epsilon_0 - r\alpha(1+\nu)T(r,t)], \quad (4.7)$$

$$\sigma_\theta = \frac{2G}{r(1-2\nu)} [(1-\nu)u + r\nu u' + r\nu\epsilon_0 - r\alpha(1+\nu)T(r,t)]. \quad (4.8)$$

Inserting the stresses in Eqs. (4.7) and (4.8) into the equation of motion (4.3), one obtains the nonhomogenous Euler equation for radial displacement

$$r^2 \frac{d^2 u}{dr^2} + r \frac{du}{dr} - u = -\frac{r^2}{(1-\nu)} \left[\frac{1-2\nu}{2G} \rho \omega^2 r - \alpha(1+\nu)T'(r,t) \right]. \quad (4.9)$$

Solution of homogeneous part of this equation is obtained effortlessly as

$$u_h = \frac{C_1}{r} + C_2 r, \quad (4.10)$$

in which C_1 and C_2 are arbitrary integration constants. The particular solution of the problem is integrated by the method of variation of parameters since the equation is suitable to the form of

$$\frac{d^2 u}{dr^2} + \frac{1}{r} \frac{du}{dr} - \frac{u}{r^2} = F(r). \quad (4.11)$$

as given in [72]. In this method, particular solution of the equation is obtained by using

$$u_p(r) = Y_1(r)u_1(r) + Y_2(r)u_2(r), \quad (4.12)$$

where $Y_1(r)$ and $Y_2(r)$ are defined by using homogeneous solution of the problem (4.10) as

$$Y_1(r) = \frac{1}{r}, \quad (4.13)$$

$$Y_2(r) = r, \quad (4.14)$$

and

$$u_1(r) = -\int \frac{Y_2(r)F(r)}{W(r)} dr, \quad (4.15a)$$

$$u_2(r) = \int \frac{Y_1(r)F(r)}{W(r)} dr, \quad (4.15b)$$

in which Wronskian of the system is obtained by using

$$W(r) = Y_1(r) \frac{dY_2(r)}{dr} - \frac{dY_1(r)}{dr} Y_2(r), \quad (4.16)$$

as

$$W(r) = \frac{2}{r}. \quad (4.17)$$

and $F(r)$ is the non-homogeneous part of the equation as

$$F(r) = -\frac{1}{(1-\nu)} \left[\frac{1-2\nu}{2G} \rho \omega^2 r - \alpha(1+\nu) T'(r, t) \right]. \quad (4.18)$$

Hence, particular solution is integrated as

$$u_p = -\frac{(1-2\nu)\rho\omega^2 r^3}{16G(1-\nu)} + \frac{\alpha(1+\nu)}{r(1-\nu)} \int_0^r T(\xi, t) \xi d\xi. \quad (4.19)$$

The integral involved in this equation can be evaluated analytically. The result is

$$\int_0^r \bar{T}(\xi, t) \xi d\xi = \frac{T_m}{t_t} \left[\left(t - \frac{b^2}{4\kappa} + \frac{r^2}{8\kappa} \right) \frac{r^2}{2} + \frac{2}{\kappa b} \sum_{n=1}^{\infty} e^{-\kappa\gamma_n^2 t} \frac{r J_1(r\gamma_n)}{\gamma_n^4 J_1(b\gamma_n)} \right]. \quad (4.20)$$

For the general solution of the Eq. (4.9),

$$u = u_h + u_p \quad (4.21)$$

is used. The result is

$$u = \frac{C_1}{r} + C_2 r - \frac{(1-2\nu)\rho\omega^2 r^3}{16G(1-\nu)} + \frac{\alpha(1+\nu)}{r(1-\nu)} \int_0^r T(\xi, t) \xi d\xi. \quad (4.22)$$

From Eqs. (4.7) and (4.8), radial and circumferential stress components are derived as

$$\begin{aligned} \sigma_r = & -\frac{2GC_1}{r^2} + \frac{2G}{1-2\nu} (C_2 + \nu\epsilon_0) - \frac{1}{8(1-\nu)} \left[(3-2\nu)\rho\omega^2 r^2 \right. \\ & \left. + \frac{16G\alpha(1+\nu)}{r^2} \int_0^r T(\xi, t) \xi d\xi \right], \end{aligned} \quad (4.23)$$

$$\begin{aligned} \sigma_\theta = & \frac{2GC_1}{r^2} + \frac{2G}{1-2\nu} (C_2 + \nu\epsilon_0) - \frac{1}{8(1-\nu)} \left\{ (1+2\nu)\rho\omega^2 r^2 \right. \\ & \left. + \frac{16G\alpha(1+\nu)}{r^2} \left[r^2 T(r, t) - \int_0^r T(\xi, t) \xi d\xi \right] \right\}. \end{aligned} \quad (4.24)$$

Then, substituting these stresses into Eq. (4.6) gives

$$\sigma_z = \frac{2G}{1-2\nu} [2\nu C_2 + (1-\nu)\epsilon_0] - \frac{1}{2(1-\nu)} [\nu\rho\omega^2 r^2 + 4G\alpha(1+\nu)T(r, t)]. \quad (4.25)$$

The solution presented here is in agreement with those in [12],[44],[45]. On the other hand, it should be mentioned that as $r \rightarrow 0$ (at the center of the shaft) the terms containing the temperature $T(r, t)$ are finite in all equations in consistence with the physics of the problem. In this context, following integrals that are located in the equations are calculated in the limiting case by L'Hopital's Rule to prevent computational singularity [4]

$$\lim_{r \rightarrow 0} \left[\frac{1}{r} \int_0^r T(\xi, t) \xi d\xi \right] = \lim_{r \rightarrow 0} rT(r, t) = 0, \quad (4.26)$$

$$\lim_{r \rightarrow 0} \left[\frac{1}{r^2} \int_0^r T(\xi, t) \xi d\xi \right] = \lim_{r \rightarrow 0} \frac{rT(r, t)}{2r} = \frac{T(0, t)}{2}. \quad (4.27)$$

Finally, axial force is determined by assuming the elastic region is bounded in $\delta \leq r \leq \lambda$ with help of Eq. (4.25)

$$F_z^e = 2\pi \int_{\delta}^{\lambda} \sigma_z r dr = 2\pi \left\{ \frac{G(\lambda^2 - \delta^2)}{1 - 2\nu} [2\nu C_2 + (1 - \nu)\epsilon_0] - \frac{1}{8(1 - \nu)} \left[(\lambda^4 - \delta^4) \nu \rho \omega^2 + 16G\alpha(1 + \nu) \int_{\delta}^{\lambda} T(\xi, t) \xi d\xi \right] \right\}, \quad (4.28)$$

to make use of condition (3.2) for further calculations.

4.3 Plastic (Edge Regime) Region I

In the plastic region I, the stress state is in an edge regime of Tresca's hexagon in the principal stress space with the inequality of $\sigma_r = \sigma_{\theta} > \sigma_z$. Hence, Tresca's yield condition leads to

$$\sigma_{\theta} - \sigma_z = \sigma_{th}, \quad \sigma_r - \sigma_z = \sigma_{th}, \quad (4.29)$$

where σ_{th} is the yield stress and as defined in Eq. (3.5). Accordingly, for this plastic region, Tresca's yielding functions are described as

$$f_1 = \sigma_{\theta} - \sigma_z - \sigma_{th} = 0, \quad (4.30)$$

$$f_2 = \sigma_r - \sigma_z - \sigma_{th} = 0. \quad (4.31)$$

The flow rule associated with the yielding condition reads

$$d\epsilon_i^p = \sum_{j=1}^2 \frac{\partial f_j}{\partial \sigma_i} d\lambda_j, \quad (4.32)$$

where the subscript i denotes a principal direction and $d\lambda_j$ is a positive scalar factor of proportionality [65]. Hence, for this plastic region, plastic strain increments are

$$d\epsilon_r^p = \frac{\partial f_1}{\partial \sigma_r} d\lambda_1 + \frac{\partial f_2}{\partial \sigma_r} d\lambda_2 = d\lambda_2, \quad (4.33)$$

$$d\epsilon_\theta^p = \frac{\partial f_1}{\partial \sigma_\theta} d\lambda_1 + \frac{\partial f_2}{\partial \sigma_\theta} d\lambda_2 = d\lambda_1, \quad (4.34)$$

$$d\epsilon_z^p = \frac{\partial f_1}{\partial \sigma_z} d\lambda_1 + \frac{\partial f_2}{\partial \sigma_z} d\lambda_2 = -d\lambda_1 - d\lambda_2. \quad (4.35)$$

Furthermore in case of a monotonically increasing load parameters, the radial and circumferential plastic strains are positive ($\epsilon_r^p > 0$ and $\epsilon_\theta^p > 0$), and axial plastic strain is the negative sum of the other two directions due to the plastic incompressibility

$$\epsilon_z^p = -(\epsilon_r^p + \epsilon_\theta^p). \quad (4.36)$$

According to the yield condition (4.29), circumferential and axial stresses can be expressed in term of radial stress as

$$\sigma_\theta = \sigma_r, \quad (4.37)$$

$$\sigma_z = \sigma_r - \sigma_{th}. \quad (4.38)$$

Inserting Eq. (4.37) into the equation of motion (4.3) gives

$$r\sigma_r' + \rho\omega^2 r^2 = 0. \quad (4.39)$$

Integration of this equation leads to

$$\sigma_r = C_3 - \frac{1}{2}\rho\omega^2 r^2, \quad (4.40)$$

where C_3 is an integration constant. It should be also kept in mind that $\sigma_\theta = \sigma_r$. In order to find out axial stress component, Eqs. (3.5) and (4.38) are combined:

$$\sigma_z = C_3 - \frac{1}{2}\rho\omega^2 r^2 - \sigma_0 [1 - \beta T(r, t)]. \quad (4.41)$$

By taking into account plane strain assumption (3.4) and geometric relations (4.4), summation of strains can be displayed as (see [73])

$$\epsilon_r + \epsilon_\theta + \epsilon_z = u' + \frac{u}{r} + \epsilon_0. \quad (4.42)$$

Here, each strain can be written in terms of stresses and plastic strains by using Hooke's law (4.5). Furthermore, summation of the plastic strains equals zero because

of plastic incompressibility (4.36). Hence, only stress terms remain in the equation. This equation and additionally Eqs. (4.37), (4.40) and (4.41) are used to derive first order linear differential equation for radial displacement:

$$u' + \frac{u}{r} = \frac{1}{4G(1+\nu)} \left\{ (1-2\nu) (6C_3 - 2\sigma_0 - 3\rho\omega^2 r^2) + 2[6G\alpha(1+\nu) + \beta(1-2\nu)\sigma_0] T(r,t) \right\} - \epsilon_0. \quad (4.43)$$

This equation is in the form of linear Bernoulli equation [72] as

$$u' + p(r)u = q(r), \quad (4.44)$$

with the solution of

$$u = \frac{1}{a(r)} \int a(r)q(r)dr + \frac{C}{a(r)}, \quad (4.45)$$

where C is a constant and $a(r)$ is defined as

$$a(r) = e^{\int p(r)dr}. \quad (4.46)$$

In Eq. (4.43)

$$p(r) = \frac{1}{r}, \quad (4.47)$$

$$a(r) = r, \quad (4.48)$$

$$q(r) = \frac{1}{4G(1+\nu)} \left\{ (1-2\nu) (6C_3 - 2\sigma_0 - 3\rho\omega^2 r^2) + 2[6G\alpha(1+\nu) + \beta(1-2\nu)\sigma_0] T(r,t) \right\} - \epsilon_0. \quad (4.49)$$

The general solution is adapted as

$$u = \frac{C_4}{r} - \frac{\epsilon_0 r}{2} + \frac{1}{4Gr(1+\nu)} \left\{ \frac{(1-2\nu)r^2}{4} (12C_3 - 4\sigma_0 - 3\rho\omega^2 r^2) + 2[6G\alpha(1+\nu) + \beta(1-2\nu)\sigma_0] \int_0^r T(\xi,t) \xi d\xi \right\}, \quad (4.50)$$

in which C_4 is fourth integration constant of the problem. The integral here has been evaluated before and given in Eq. (4.20). The plastic parts of the strains are found as the differences of the total strains and their elastic and thermal parts together with Eqs. (4.4), (4.37), (4.40), (4.41) and (4.50) as

$$\begin{aligned} \epsilon_r^p = & -\frac{C_4}{r^2} - \frac{\epsilon_0}{2} + \frac{1}{16G(1+\nu)} \left\{ (1-2\nu) (4C_3 - 5\rho\omega^2 r^2) - 4\sigma_0 \right. \\ & \left. - \frac{8[6G\alpha(1+\nu) + \beta(1-2\nu)\sigma_0]}{r^2} \int_0^r T(\xi,t) \xi d\xi \right. \\ & \left. + 8[4G\alpha(1+\nu) + \beta(1-\nu)\sigma_0] T(r,t) \right\}, \end{aligned} \quad (4.51)$$

$$\begin{aligned}\epsilon_{\theta}^p &= \frac{C_4}{r^2} - \frac{\epsilon_0}{2} + \frac{1}{16G(1+\nu)} \left\{ (1-2\nu)(4C_3 + \rho\omega^2 r^2) - 4\sigma_0 \right. \\ &\quad \left. + \frac{8[6G\alpha(1+\nu) + \beta(1-2\nu)\sigma_0]}{r^2} \int_0^r T(\xi, t) \xi d\xi \right. \\ &\quad \left. - 8[2G\alpha(1+\nu) - \beta\nu\sigma_0] T(r, t) \right\},\end{aligned}\quad (4.52)$$

$$\epsilon_z^p = \frac{(1-2\nu)(\rho\omega^2 r^2 - 2C_3) + 2\sigma_0}{4G(1+\nu)} + \epsilon_0 - \left[\alpha + \frac{\beta\sigma_0}{2G(1+\nu)} \right] T(r, t). \quad (4.53)$$

The axial force integral for the plastic region I is calculated with the help of Eq. (4.41)

as

$$\begin{aligned}F_z^{PI} &= 2\pi \int_{\delta}^{\lambda} \sigma_z r dr = 2\pi \left\{ \frac{(\lambda^2 - \delta^2)}{2} \left[C_3 - \sigma_0 - \frac{(\lambda^2 + \delta^2)\rho\omega^2}{4} \right] \right. \\ &\quad \left. + \beta\sigma_0 \int_{\delta}^{\lambda} T(\xi, t) \xi d\xi \right\}.\end{aligned}\quad (4.54)$$

Here, it should be noted that all expressions that are derived in this region for $T(r, t) = 0$, recovers the equations given in [12].

4.4 Plastic (Side Regime) Region II

Governing equation for this region is obtained by a procedure similar to the one outlined in [21] as following. In plastic region II, the principal stresses satisfy $\sigma_{\theta} > \sigma_r > \sigma_z$. The stress image points are on a side regime of Tresca's hexagon in principal stress space. At this point, the yield condition takes the form

$$\sigma_{\theta} - \sigma_z = \sigma_{th}. \quad (4.55)$$

Accordingly, for this plastic region Tresca's yielding function is described by

$$f_1 = \sigma_{\theta} - \sigma_z - \sigma_{th} = 0. \quad (4.56)$$

By making use of Eq. (4.32) plastic strain increments become

$$d\epsilon_r^p = \frac{\partial f_1}{\partial \sigma_r} d\lambda_1 = 0, \quad (4.57)$$

$$d\epsilon_{\theta}^p = \frac{\partial f_1}{\partial \sigma_{\theta}} d\lambda_1 = d\lambda_1, \quad (4.58)$$

$$d\epsilon_z^p = \frac{\partial f_1}{\partial \sigma_z} d\lambda_1 = -d\lambda_1. \quad (4.59)$$

and plastic strains satisfy $\epsilon_r^p = 0$, $\epsilon_{\theta}^p > 0$, and $\epsilon_z^p < 0$. In the absence of plastic

predeformation, the associated flow rule becomes

$$\epsilon_r^p = 0, \quad (4.60)$$

$$\epsilon_\theta^p = -\epsilon_z^p. \quad (4.61)$$

Hence, the radial strain consists of an elastic and thermal parts only:

$$\epsilon_r = \frac{1}{2(1+\nu)G} [\sigma_r - \nu(\sigma_\theta + \sigma_z)] + \alpha T. \quad (4.62)$$

Here and further, axial stress is eliminated by using

$$\sigma_z = \sigma_\theta - \sigma_{th}, \quad (4.63)$$

that is obtained from yield condition (4.55). Thus, axial plastic strain component may be expressed by using Eqs. (4.5c) and (3.5) as

$$\epsilon_z^p = \epsilon_0 + \frac{\nu\sigma_r - (1-\nu)\sigma_\theta + \sigma_0(1-\beta T)}{2G(1+\nu)} - \alpha T. \quad (4.64)$$

By using Eq. (4.64) circumferential strain leads to

$$\epsilon_\theta = -\epsilon_0 - \frac{1}{G(1+\nu)} \left\{ \nu\sigma_r - (1-\nu) \left[\sigma_\theta - \frac{\sigma_0}{2}(1-\beta T) \right] \right\} + 2\alpha T. \quad (4.65)$$

Then Eqs. (4.62) and (4.65) are substituted into geometric relations (4.4) to get

$$\sigma_r = \frac{2G}{(1-2\nu)r} [\nu(u + \epsilon_0 r) + (1-\nu)u'r - \alpha(1+\nu)rT(r, t)], \quad (4.66)$$

$$\begin{aligned} \sigma_\theta = & \frac{1}{2(1-2\nu)} \left\{ 2G \left(\frac{u}{r} + 2\nu u' + \epsilon_0 \right) + (1-2\nu)\sigma_0 \right. \\ & \left. - [4G\alpha(1+\nu) + \beta(1-2\nu)\sigma_0] T(r, t) \right\}. \end{aligned} \quad (4.67)$$

Inserting these equations into Eq. (4.3) field equation for plastic region II is obtained:

$$\begin{aligned} r^2 u'' + ru' - \frac{u}{2(1-\nu)} = & \frac{r}{4G(1-\nu)} [(1-2\nu)(2G\epsilon_0 + \sigma_0 - 2\rho\omega^2 r^2) \\ & - \beta(1-2\nu)\sigma_0 T(r, t) + 4G\alpha(1+\nu) \\ & \times rT'(r, t)]. \end{aligned} \quad (4.68)$$

Solution of homogeneous part of field equation is

$$u_h = C_5 r^M + \frac{C_6}{r^M}, \quad (4.69)$$

where C_5 and C_6 are arbitrary integration constants and

$$M = \sqrt{\frac{1}{2(1-\nu)}}. \quad (4.70)$$

For the particular solution, method of Variation of parameter is used as defined in the elastic region. For $Y_1(r) = r^M$, and $Y_2(r) = 1/r^M$, Wronksian is calculated by using Eq. (4.16) as

$$W(r) = \frac{-2M}{r}. \quad (4.71)$$

In Eq. (4.68), it is visible that

$$F(r) = \frac{1}{r^2} \left\{ \frac{r}{4G(1-\nu)} [(1-2\nu)(2G\epsilon_0 + \sigma_0 - 2\rho\omega^2 r^2) - \beta(1-2\nu)\sigma_0 T(r,t) + 4G\alpha(1+\nu)rT'(r,t)] \right\}. \quad (4.72)$$

By using Eqs. (4.12) and (4.15) particular solution is compiled as

$$u_p = \epsilon_0 r - \frac{(1-2\nu)\rho\omega^2 r^3}{G(17-18\nu)} + \frac{\sigma_0}{2G} \left\{ r - \frac{\beta(1-2\nu)}{4M(1-\nu)} \left[r^M \int_0^r T(\xi,t) \xi^{-M} d\xi - r^{-M} \int_0^r T(\xi,t) \xi^M d\xi \right] \right\} + \frac{\alpha(1+\nu)}{2M(1-\nu)} \left[r^M \int_0^r \frac{\partial T(\xi,t)}{\partial \xi} \xi^{1-M} d\xi - r^{-M} \int_0^r \frac{\partial T(\xi,t)}{\partial \xi} \xi^{1+M} d\xi \right]. \quad (4.73)$$

Integration by parts is applied to get rid of derivatives of temperature in the integrals and following solutions are obtained

$$\int_0^r \frac{\partial T(\xi,t)}{\partial \xi} \xi^{1-M} d\xi = r^{1-M} T(r,t) - (1-M) \int_0^r T(\xi,t) \xi^{-M} d\xi, \quad (4.74)$$

$$\int_0^r \frac{\partial T(\xi,t)}{\partial \xi} \xi^{1+M} d\xi = r^{1+M} T(r,t) - (1+M) \int_0^r T(\xi,t) \xi^M d\xi. \quad (4.75)$$

The integrals in Eqs. (4.74) and (4.75) are amenable to analytical treatment. The results are

$$\int_0^r \bar{T}(\xi,t) \xi^M d\xi = \frac{T_m}{t} \left\{ \frac{r^{1+M} [(1+M)r^2 - (3+M)(b^2 - 4\kappa t)]}{4\kappa(1+M)(3+M)} + \frac{2}{\kappa b(1+M)} \sum_{n=1}^{\infty} e^{-\kappa\gamma_n^2 t} \frac{r^{1+M} F_H(a_1, a_2, a_3; z)}{\gamma_n^3 J_1(b\gamma_n)} \right\}, \quad (4.76)$$

where $F_H(a_1, a_2, a_3; z)$ is a hypergeometric function and is described as

$$F_H(a_1, a_2, a_3; z) = 1 + \frac{a_1}{a_2 a_3} z + \frac{a_1(1+a_1)}{2a_2(1+a_2)a_3(1+a_3)} z^2 + \frac{a_1(1+a_1)(2+a_1)}{6a_2(1+a_2)(2+a_2)a_3(1+a_3)(2+a_3)} z^3 + \dots \quad (4.77)$$

and where

$$a_1 = \frac{1}{2} + \frac{M}{2}, \quad (4.78)$$

$$a_2 = 1, \quad (4.79)$$

$$a_3 = \frac{3}{2} + \frac{M}{2}, \quad (4.80)$$

$$z = -\frac{1}{4}r^2\gamma_n^2. \quad (4.81)$$

and

$$\int_0^r \bar{T}(\xi, t) \xi^{-M} d\xi = \frac{T_m}{t_t} \left\{ \frac{r^{1-M} [(1-M)r^2 - (3-M)(b^2 - 4\kappa t)]}{4\kappa(1-M)(3-M)} + \frac{2}{\kappa b(1-M)} \sum_{n=1}^{\infty} e^{-\kappa\gamma_n^2 t} \frac{r^{1-M} F_H(a_1, a_2, a_3; z)}{\gamma_n^3 J_1(b\gamma_n)} \right\}, \quad (4.82)$$

where $F_H(a_1, a_2, a_3; z)$ is same as in Eq. (4.77) and

$$a_1 = \frac{1}{2} - \frac{M}{2}, \quad (4.83)$$

$$a_2 = 1, \quad (4.84)$$

$$a_3 = \frac{3}{2} - \frac{M}{2}, \quad (4.85)$$

$$z = -\frac{1}{4}r^2\gamma_n^2. \quad (4.86)$$

After some simplification and with Eq. (4.21), radial displacement is acquired as

$$u = C_5 r^M + \frac{C_6}{r^M} + r \left(\epsilon_0 + \frac{\sigma_0}{2G} \right) - \frac{(1-2\nu)\rho\omega^2 r^3}{G(17-18\nu)} + \frac{1}{8GM(1-\nu)} \left\{ \frac{4G\alpha(1+M)(1+\nu) + \beta(1-2\nu)\sigma_0}{r^M} \int_0^r T(\xi, t) \xi^M d\xi - r^M [4G\alpha(1-M)(1+\nu) + \beta(1-2\nu)\sigma_0] \int_0^r T(\xi, t) \xi^{-M} d\xi \right\}. \quad (4.87)$$

Substituting radial displacement and its radial derivative into Eqs. (4.66) and (4.67) gives radial and circumferential stresses

$$\begin{aligned} \sigma_r = & \frac{2G}{(1-2\nu)r} \left\{ C_5 [M(1-\nu) + \nu] r^M - C_6 [M(1-\nu) - \nu] r^{-M} + (1+\nu)\epsilon_0 r + \frac{\sigma_0 r}{2G} \right\} - \frac{2(3-2\nu)\rho\omega^2 r^2}{17-18\nu} - \frac{1}{4M(1-\nu)(1-2\nu)r} \left\{ [M(1-\nu) + \nu] \right. \\ & \times [4G\alpha(1-M)(1+\nu) + \beta(1-2\nu)\sigma_0] r^M \int_0^r T(\xi, t) \xi^{-M} d\xi \\ & + \frac{[M(1-\nu) - \nu] [4G\alpha(1+M)(1+\nu) + \beta(1-2\nu)\sigma_0]}{r^M} \\ & \left. \times \int_0^r T(\xi, t) \xi^M d\xi \right\}, \quad (4.88) \end{aligned}$$

$$\begin{aligned}
\sigma_\theta = & \frac{G}{(1-2\nu)r} \left[C_5(1+2M\nu)r^M + C_6(1-2M\nu)r^{-M} + 2(1+\nu)\epsilon_0r \right. \\
& \left. + \frac{\sigma_0r}{G} \right] - \frac{(1+6\nu)\rho\omega^2r^2}{17-18\nu} - \frac{1}{8M(1-\nu)(1-2\nu)r} \left\{ (1+2M\nu) \right. \\
& \times [4G\alpha(1-M)(1+\nu) + \beta(1-2\nu)\sigma_0] r^M \int_0^r T(\xi,t)\xi^{-M}d\xi \\
& \left. - \frac{(1-2M\nu)[4G\alpha(1+M)(1+\nu) + \beta(1-2\nu)\sigma_0]}{r^M} \int_0^r T(\xi,t)\xi^M d\xi \right\} \\
& - \frac{4G\alpha(1+\nu) + \beta(1-\nu)\sigma_0}{2(1-\nu)} T(r,t). \tag{4.89}
\end{aligned}$$

Axial stress component is obtained by making use of Eq. (4.63) as

$$\begin{aligned}
\sigma_z = & \frac{G}{(1-2\nu)r} \left[C_5(1+2M\nu)r^M + C_6(1-2M\nu)r^{-M} + 2(1+\nu)\epsilon_0r \right. \\
& \left. + \frac{2\nu\sigma_0r}{G} \right] - \frac{(1+6\nu)\rho\omega^2r^2}{17-18\nu} - \frac{1}{8M(1-\nu)(1-2\nu)r} \left\{ (1+2M\nu) \right. \\
& \times [4G\alpha(1-M)(1+\nu) + \beta(1-2\nu)\sigma_0] r^M \int_0^r T(\xi,t)\xi^{-M}d\xi \\
& \left. - \frac{(1-2M\nu)[4G\alpha(1+M)(1+\nu) + \beta(1-2\nu)\sigma_0]}{r^M} \int_0^r T(\xi,t)\xi^M d\xi \right\} \\
& - \frac{4G\alpha(1+\nu) - \beta(1-\nu)\sigma_0}{2(1-\nu)} T(r,t). \tag{4.90}
\end{aligned}$$

Finally, axial and circumferential plastic strains are derived with the help of Eqs. (4.61) and (4.64) as

$$\begin{aligned}
\epsilon_z^p = & -\epsilon_\theta^p = -\frac{1}{2r} \left(C_5r^M + \frac{C_6}{r^M} \right) + \frac{(1-2\nu)\rho\omega^2r^2}{2G(17-18\nu)} \\
& + \frac{1}{16GM(1-\nu)r} \left\{ [4G\alpha(1-M)(1+\nu) + \beta(1-2\nu)\sigma_0] r^M \right. \\
& \times \int_0^r T(\xi,t)\xi^{-M}d\xi - \frac{[4G\alpha(1+M)(1+\nu) + \beta(1-2\nu)\sigma_0]}{r^M} \\
& \left. \times \int_0^r T(\xi,t)\xi^M d\xi \right\} - \frac{\beta\sigma_0}{4G} T(r,t). \tag{4.91}
\end{aligned}$$

Axial force integral is more complicated than those of previous regions because of the necessity for evaluation of double integrals that are obtained by using Eq. (3.2).

Method of integration by parts helps to transform double integrals into single ones as

$$\begin{aligned} \int_{\delta}^{\lambda} r^{-M} \left(\int_0^r T(\xi, t) \xi^M d\xi \right) dr &= \frac{\lambda^{1-M}}{1-M} \int_0^{\lambda} T(\xi, t) \xi^M d\xi \\ &\quad - \frac{\delta^{1-M}}{1-M} \int_0^{\delta} T(\xi, t) \xi^M d\xi \\ &\quad - \frac{1}{1-M} \int_{\delta}^{\lambda} T(\xi, t) \xi d\xi, \end{aligned} \quad (4.92)$$

$$\begin{aligned} \int_{\delta}^{\lambda} r^M \left(\int_0^r T(\xi, t) \xi^{-M} d\xi \right) dr &= \frac{\lambda^{1+M}}{1+M} \int_0^{\lambda} T(\xi, t) \xi^{-M} d\xi \\ &\quad - \frac{\delta^{1+M}}{1+M} \int_0^{\delta} T(\xi, t) \xi^{-M} d\xi \\ &\quad - \frac{1}{1+M} \int_{\delta}^{\lambda} T(\xi, t) \xi d\xi. \end{aligned} \quad (4.93)$$

With the help of these integrations and after some simplifications, axial force integral for plastic region II is calculated as

$$\begin{aligned} F_z^{PII} &= 2\pi \left\{ \frac{1}{1-2\nu} \left\{ \frac{(\lambda^{1+M} - \delta^{1+M})(1+2M\nu)GC_5}{1+M} \right. \right. \\ &\quad \left. \left. + \frac{(\lambda^{1-M} - \delta^{1-M})(1-2M\nu)GC_6}{1-M} + (\lambda^2 - \delta^2)[(1+\nu)G\epsilon_0 + \nu\sigma_0] \right\} \right. \\ &\quad - \frac{(\lambda^4 - \delta^4)(1+6\nu)\rho\omega^2}{4(17-18\nu)} - \frac{S_1}{1+M} \left[\lambda^{1+M} \int_0^{\lambda} T(\xi, t) \xi^{-M} d\xi \right. \\ &\quad \left. - \delta^{1+M} \int_0^{\delta} T(\xi, t) \xi^{-M} d\xi \right] + \frac{S_2}{1-M} \left[\lambda^{1-M} \int_0^{\lambda} T(\xi, t) \xi^M d\xi \right. \\ &\quad \left. - \delta^{1-M} \int_0^{\delta} T(\xi, t) \xi^M d\xi \right] + \left(\frac{S_1}{1+M} - \frac{S_2}{1-M} - S_3 \right) \\ &\quad \left. \times \int_{\delta}^{\lambda} T(\xi, t) \xi d\xi \right\}, \end{aligned} \quad (4.94)$$

in which

$$S_1 = \frac{(1+2M\nu)[4(1-M)(1+\nu)G\alpha + (1-2\nu)\sigma_0\beta]}{8M(1-\nu)(1-2\nu)}, \quad (4.95)$$

$$S_2 = \frac{(1-2M\nu)[4(1+M)(1+\nu)G\alpha + (1-2\nu)\sigma_0\beta]}{8M(1-\nu)(1-2\nu)}, \quad (4.96)$$

$$S_3 = \frac{4(1+\nu)G\alpha - (1-\nu)\sigma_0\beta}{2(1-\nu)}. \quad (4.97)$$

4.5 Predeformed Elastic Region

Predeformed elastic region is an elastic region that includes permanent plastic deformations, which have been occurred in elastic-plastic state. It becomes valid after

the unloading starts. Formulation of this region is identical with the elastic region. However, permanent plastic strains, i.e., ϵ_i^{pr} , are included in this region [16]. In formulation, by using plastic incompressibility

$$\epsilon_z^{pr} = -(\epsilon_r^{pr} + \epsilon_\theta^{pr}), \quad (4.98)$$

and with help of Hooke's law in axial direction (4.5c), axial stress is obtained as

$$\sigma_z = \nu(\sigma_r + \sigma_\theta) + 2G(1 + \nu) [\epsilon_0 + \epsilon_r^{pr} + \epsilon_\theta^{pr} - \alpha T(r, t)]. \quad (4.99)$$

Substituting this expression into Eqs. (4.5a) and (4.5b) and using Eq. (4.4) gives

$$\sigma_r = \frac{2G}{r(1 - 2\nu)} \left\{ \nu u + r(1 - \nu)u' + r[(1 - 2\nu)\epsilon_r^{pr} - \nu\epsilon_0] - r\alpha(1 + \nu)T(r, t) \right\}, \quad (4.100)$$

$$\sigma_\theta = \frac{2G}{r(1 - 2\nu)} \left\{ (1 - \nu)u + r\nu u' - r[(1 - 2\nu)\epsilon_\theta^{pr} - \nu\epsilon_0] - r\alpha(1 + \nu)T(r, t) \right\}. \quad (4.101)$$

Inserting these stress expressions into equation of motion, Eq. (4.3), gives governing differential equation for displacement

$$r^2 \frac{d^2 u}{dr^2} + r \frac{du}{dr} - u = -\frac{(1 - 2\nu)\rho\omega^2 r^3}{2G(1 - \nu)} + \frac{r}{1 - \nu} \left\{ (1 - 2\nu)(\epsilon_r^{pr} + r\epsilon_r^{pr'} - \epsilon_\theta^{pr}) + r\alpha(1 + \nu)T'(r, t) \right\}, \quad (4.102)$$

which assures the solution

$$u = \frac{C_1^*}{r} + C_2^* r - \frac{(1 - 2\nu)\rho\omega^2 r^3}{16G(1 - \nu)} + \frac{(1 - 2\nu)}{2(1 - \nu)} \left[r \int_0^r \frac{\epsilon_r^{pr} - \epsilon_\theta^{pr}}{\xi} d\xi + \frac{1}{r} \int_0^r \xi (\epsilon_r^{pr} + \epsilon_\theta^{pr}) d\xi \right] + \frac{\alpha(1 + \nu)}{r(1 - \nu)} \int_0^r T(\xi, t) \xi d\xi, \quad (4.103)$$

where C_1^* and C_2^* are new integration constants. The stresses are obtained as (compare with [16])

$$\sigma_r = -\frac{2GC_1^*}{r^2} + \frac{2G}{1 - 2\nu} (C_2^* + \nu\epsilon_0) - \frac{1}{8(1 - \nu)} \left\{ (3 - 2\nu)\rho\omega^2 r^2 - 8G \left[\int_0^r \frac{\epsilon_r^{pr} - \epsilon_\theta^{pr}}{\xi} d\xi - \frac{1 - 2\nu}{r^2} \int_0^r \xi (\epsilon_r^{pr} + \epsilon_\theta^{pr}) d\xi \right] + \frac{16G\alpha(1 + \nu)}{r^2} \int_0^r T(\xi, t) \xi d\xi \right\}, \quad (4.104)$$

$$\sigma_\theta = \frac{2GC_1^*}{r^2} + \frac{2G}{1 - 2\nu} (C_2^* + \nu\epsilon_0) - \frac{1}{8(1 - \nu)} \left\{ (1 + 2\nu)\rho\omega^2 r^2 + 8G \left[-2\nu\epsilon_r^{pr} + 2(1 - \nu)\epsilon_\theta^{pr} - \int_0^r \frac{\epsilon_r^{pr} - \epsilon_\theta^{pr}}{\xi} d\xi - \frac{1 - 2\nu}{r^2} \int_0^r \xi (\epsilon_r^{pr} + \epsilon_\theta^{pr}) d\xi \right] + \frac{16G\alpha(1 + \nu)}{r^2} \left[r^2 T(r, t) - \int_0^r T(\xi, t) \xi d\xi \right] \right\}, \quad (4.105)$$

$$\begin{aligned}\sigma_z = & \frac{2G}{1-2\nu} [2\nu C_2^* + (1-\nu)\epsilon_0] - \frac{1}{2(1-\nu)} [\nu\rho\omega^2 r^2 + 4G\alpha(1+\nu)T(r,t)] \\ & + \frac{2G}{1-\nu} \left[\epsilon_r^{pr} + (1-\nu)\epsilon_\theta^{pr} + \nu \int_0^r \frac{\epsilon_r^{pr} - \epsilon_\theta^{pr}}{\xi} d\xi \right].\end{aligned}\quad (4.106)$$

These equations include some integrals such as $\frac{1}{r^2} \int_0^r f(\xi) d\xi$ and $\frac{1}{r} \int_0^r f(\xi) d\xi$. These integrals are not singular at $r = 0$. By taking limit as $r \rightarrow 0$ and using L'Hopital's rule, it can easily be shown that

$$\lim_{r \rightarrow 0} \frac{1}{r} \int_0^r \xi (\epsilon_r^{pr} + \epsilon_\theta^{pr}) d\xi = 0, \quad (4.107)$$

$$\lim_{r \rightarrow 0} \frac{1}{r^2} \int_0^r \xi (\epsilon_r^{pr} + \epsilon_\theta^{pr}) d\xi = \frac{\epsilon_r^{pr} + \epsilon_\theta^{pr}}{2}. \quad (4.108)$$

Addition to these limiting cases, Eqs. (4.26) and (4.27) are valid in this region as well. Force integral for this region will be determined in the range $0 \leq r \leq b$ which is used in unloaded state:

$$\begin{aligned}F_z^{pde} = & 2\pi \int_0^b \sigma_z r dr = 2\pi \left\{ \frac{b^2 G [2\nu C_2^* + (1-\nu)\epsilon_0]}{(1-2\nu)} \right. \\ & - \frac{b^4 \nu \rho \omega^2 + 16G\alpha(1+\nu) \int_0^b T(\xi, t) \xi d\xi}{8(1-\nu)} \\ & + \frac{2G}{1-\nu} \left\{ \nu \left[\frac{b^2}{2} \int_0^b \frac{\epsilon_r^{pr} - \epsilon_\theta^{pr}}{\xi} d\xi - \frac{1}{2} \int_0^b \xi (\epsilon_r^{pr} - \epsilon_\theta^{pr}) d\xi \right] \right. \\ & \left. \left. + \int_0^b \xi \epsilon_r^{pr} d\xi + (1-\nu) \int_0^b \xi \epsilon_\theta^{pr} d\xi \right\} \right\}.\end{aligned}\quad (4.109)$$

CHAPTER 5

EVOLUTION OF STRESSES DURING TEMPERATURE CYCLE

5.1 Purely Elastic State

Initially, the entire shaft is in a purely elastic state. Hence, the distribution of displacement and stresses are described by Eqs. (4.22–4.25). These equations contain three unknowns C_1 , C_2 , and ϵ_0 that have to be determined. With the help of boundary conditions (3.1–3.3), it is possible to obtain analytical expressions for these unknowns. From condition (3.3) there follows immediately

$$C_1 = 0, \quad (5.1)$$

to assure that the mechanical variables are finite at the center. Simultaneous solution of Eqs. (4.23) and (4.28) with substitution of $\delta = 0$ and $\lambda = b$ reveals that

$$C_2 = \frac{1}{(1-\nu)} \left[\frac{(3-5\nu)\rho\omega^2 b^2}{16G(1+\nu)} + \frac{\alpha(1-3\nu)}{b^2} \int_0^b rT(r,t) dr \right], \quad (5.2)$$

$$\epsilon_0 = -\frac{\nu\rho\omega^2 b^2}{4G(1+\nu)} + \frac{2\alpha}{b^2} \int_0^b rT(r,t) dr. \quad (5.3)$$

Since prior to the temperature cycle the shaft is at the reference temperature, it is subjected only to mechanical load that is caused by rotation. In increasing rotation speed, solutions show (as given in [12]) that yielding commences at the center of the shaft as soon as

$$(\sigma_\theta - \sigma_z)|_{r=0} = (\sigma_r - \sigma_z)|_{r=0} = \sigma_0. \quad (5.4)$$

By using this equality, the elastic limit rotation speed for isothermal shaft is obtained

$$\omega_e^i = \sqrt{\frac{8\sigma_0(1-\nu)}{(3-4\nu)\rho b^2}}, \quad (5.5)$$

where superscript i denotes the isothermal case. This result is in agreement with that in [12]. As described in the Introduction Chapter, shaft is rotated up to a certain angular speed smaller than ω_e^i . Thereafter, this rotation speed is kept constant and then the temperature cycle is applied to the surface of the shaft. During merely rotation, and at the beginning of the thermal loading, shaft will behave elastically. Partially plastic behavior will be observed in the later stages of the thermal loading.

5.2 Elastic-Plastic State

Plastic flow starts at the center of the shaft in the course of the temperature cycle. At time $t = t_p$, the condition $\sigma_\theta - \sigma_z = \sigma_r - \sigma_z = \sigma_{th}$ is reached at the center of the shaft due to thermal softening of the material, as a result of which plastic deformation begins. Plastic region I and plastic region II emerge simultaneously and spread into the shaft. Therefrom, the shaft consists of plastic region I in the range of $0 \leq r \leq r_1$, plastic region II in $r_1 \leq r \leq r_2$, and an elastic region in $r_2 \leq r \leq b$ with r_1 being border radius separating two plastic regions and r_2 is the one between plastic region II and elastic region. Hence, the solution of this problem necessitates the evaluation of 9 unknowns: C_1, C_2 (from elastic region), C_3, C_4 (from plastic region I), C_5, C_6 (from plastic region II), axial strain ϵ_0 , border radii r_1 and r_2 . In order to determine these unknowns, boundary conditions and interface conditions are used. Quite generally, at any border radius ten conditions of continuity can be formulated, in principle: the three principal stresses, the radial displacement, elastic parts and plastic parts of the strains (as well as their thermal parts, of course) are continuous throughout the shaft. However, the continuity of three properly chosen quantities e.g. of σ_r, σ_{th} and u implies the continuity of all the other ones [11]. Nine nonredundant boundary and interface conditions to evaluate unknowns are:

$$u^{pI}(0) = 0, \quad (5.6)$$

$$\sigma_r^e(b) = 0, \quad (5.7)$$

$$\sigma_r^{pI}(r_1) = \sigma_r^{pII}(r_1), \quad (5.8)$$

$$u^{pI}(r_1) = u^{pII}(r_1), \quad (5.9)$$

$$\sigma_r^{pII}(r_1) - \sigma_z^{pII}(r_1) = \sigma_{th}(r_1), \quad (5.10)$$

$$\sigma_r^{pII}(r_2) = \sigma_r^e(r_2), \quad (5.11)$$

$$u^{pII}(r_2) = u^e(r_2), \quad (5.12)$$

$$\sigma_\theta^e(r_2) - \sigma_z^e(r_2) = \sigma_{th}(r_2), \quad (5.13)$$

$$\int_0^{r_1} \sigma_z^{pI} r dr + \int_{r_1}^{r_2} \sigma_z^{pII} r dr + \int_{r_2}^b \sigma_z^e r dr = 0, \quad (5.14)$$

where the superscript e denotes elastic region, pI is plastic region I, and pII is plastic region II. The condition (5.14) is easily assembled with the help of already calculated integrals in Eqs. (4.54), (4.94) and (4.28) by accordingly adjusting limits of the integrals. By using conditions (5.6–5.8) and (5.11–5.13), the constants of integration, C_i ($i = 1 - 6$), can be expressed in terms of the interface radii r_1, r_2 and the axial strain ϵ_0 since the equations are linear in constants of integration:

$$\begin{aligned} C_1 = & \frac{r_2^2 b^2}{2 [(1-2\nu)r_2^2 + b^2] G} \left\{ \frac{(1-2\nu)[r_2^2 - (3-2\nu)b^2] \rho \omega^2}{8(1-\nu)} + 2(1+\nu) G \epsilon_0 \right. \\ & + \sigma_0 [1 - \beta T(r_2, t)] - \frac{2G\alpha(1+\nu)}{(1-\nu)r_2^2 b^2} \left[(1-2\nu)r_2^2 \int_0^b \xi T(\xi, t) d\xi \right. \\ & \left. \left. + b^2 \int_0^{r_2} \xi T(\xi, t) d\xi \right] \right\}, \quad (5.15) \end{aligned}$$

$$\begin{aligned} C_2 = & \frac{1-2\nu}{2 [(1-2\nu)r_2^2 + b^2] G} \left\{ \frac{[(1-2\nu)r_2^4 + (3-2\nu)b^4] \rho \omega^2}{8(1-\nu)} \right. \\ & + 2 \left(r_2^2 - \frac{b^2 \nu}{1-2\nu} \right) G \epsilon_0 + r_2^2 \sigma_0 [1 - \beta T(r_2, t)] + \frac{2G\alpha(1+\nu)}{1-\nu} \\ & \left. \times \left[\int_0^b \xi T(\xi, t) d\xi - \int_0^{r_2} \xi T(\xi, t) d\xi \right] \right\}, \quad (5.16) \end{aligned}$$

$$\begin{aligned} C_3 = & \frac{2G}{1-2\nu} \left\{ C_5 r_1^{-1+M} [M(1-\nu) + \nu] - C_6 r_1^{-1-M} [M(1-\nu) - \nu] \right. \\ & + (1+\nu) \epsilon_0 + \frac{\sigma_0}{2G} \left. \right\} + \frac{5(1-2\nu) \rho \omega^2 r_1^2}{2(17-18\nu)} - \frac{1}{4M(1-\nu)(1-2\nu)} \\ & \times \left\{ r_1^{-1+M} [M(1-\nu) + \nu] [4G\alpha(1-M)(1+\nu) + \beta(1-2\nu)\sigma_0] \right. \\ & \times \int_0^{r_1} \xi^{-M} T(\xi, t) d\xi + r_1^{-1-M} [M(1-\nu) - \nu] \\ & \left. \times [4G\alpha(1+M)(1+\nu) + \beta(1-2\nu)\sigma_0] \int_0^{r_1} \xi^M T(\xi, t) d\xi \right\}, \quad (5.17) \end{aligned}$$

$$C_4 = 0, \quad (5.18)$$

$$\begin{aligned}
C_5 = & \frac{r_2^{-M}}{2M} \left[-\frac{C_1(1-M)}{r_2} + (1+M)r_2 \left(C_2 - \frac{\sigma_0}{2G} - \epsilon_0 \right) \right. \\
& \left. - \frac{(3+M)(1-2\nu)^2 \rho \omega^2 r_2^3}{16(1-\nu)(17-18\nu)G} \right] - \frac{\alpha(1-M)(1+\nu)}{2M(1-\nu)} \left\{ r_2^{-1-M} \int_0^{r_2} \xi T(\xi, t) d\xi \right. \\
& \left. - \left[1 + \frac{\beta(1-2\nu)\sigma_0}{4G\alpha(1-M)(1+\nu)} \right] \int_0^{r_2} \xi^{-M} T(\xi, t) d\xi \right\}, \tag{5.19}
\end{aligned}$$

$$\begin{aligned}
C_6 = & \frac{r_2^M}{2M} \left[\frac{C_1(1+M)}{r_2} - (1-M)r_2 \left(C_2 - \frac{\sigma_0}{2G} - \epsilon_0 \right) \right. \\
& \left. + \frac{(3-M)(1-2\nu)^2 \rho \omega^2 r_2^3}{16(1-\nu)(17-18\nu)G} \right] + \frac{\alpha(1+M)(1+\nu)}{2M(1-\nu)} \left\{ r_2^{-1+M} \int_0^{r_2} \xi T(\xi, t) d\xi \right. \\
& \left. - \left[1 + \frac{\beta(1-2\nu)\sigma_0}{4G\alpha(1+M)(1+\nu)} \right] \int_0^{r_2} \xi^M T(\xi, t) d\xi \right\}. \tag{5.20}
\end{aligned}$$

To determine remaining unknowns, r_1 , r_2 and ϵ_0 , the nonlinear algebraic equations (5.9), (5.10) and (5.14) are solved for these unknowns by iteration. This state of stress is valid throughout the shaft until the beginning of the unloaded state.

5.3 Unloaded State

With increasing time, the expansion of the plastic zones becomes slower. In case that the shaft does not turn out fully plastic (which should be avoided in any case from the engineering point of view), its expansion ceases at time $t = t_{ub}$ when the second plastic region and elastic region border radius r_2 attains a stationary value. Thereafter, a predeformed elastic region begins to spread inwards rapidly, first into plastic region II then into plastic region I and to the center. The basic criterion for unloaded state at some radius r at time $t_u(r)$ is (see [56])

$$\left. \frac{\partial \epsilon_\theta^p(r, t)}{\partial t} \right|_{t=t_u(r)} = 0, \tag{5.21}$$

where ϵ_θ^p is described according to Eq. (4.91). Inversion of the function $t_u(r)$ yields $r_u(t)$, i.e., the time dependence of the interface radius separating the plastic and the unloaded regions. Since the plastic strains at a fixed radius are frozen with the onset of unloading at this radius, the permanent plastic strains then are given by

$$\epsilon_i^p(r) = \epsilon_i^{pr}(r) = \epsilon_i^p[r, t_u(r)]. \tag{5.22}$$

However, the calculation of $r_u(t)$ from Eq. (5.21) and of the permanent plastic strains according to Eq. (5.22) is not an easy task, since the latter enters the equations which one needs for the calculation of the stresses, which in turn, influence the plastic strain distribution. Hence, one obtains a nonlinear, coupled system of algebraic and differential equations. In the related plane stress problem [74] such a system was treated iteratively by a time-discretization of the equation analogous to Eq. (5.21), and in [56] a quite concise treatment based on a universal expression for the displacement field was possible. A necessary prerequisite for this universal expression is the absence of plastic flow in the axial direction, which however in the present case does occur. On the other hand, in contrast to [74], the axial strain has to be found with the help of condition (3.2), too, which represents an additional coupling between the unknowns. Hence, a rigorous treatment of the unloading process could be performed in finite time steps requiring a very complex algorithm only, the achievable accuracy of which – in view of the fast unloading process – remains an open question. Therefore, unloading is treated in an approximate way by assuming sudden unloading in the entire plastic core at time t_{ub} , at which the expansion of the plastic zone ends. Thus, in the final stage the permanent plastic strains in Eqs. (4.103–4.106) are given by $\epsilon_i^p(r) = \epsilon_i^{pr}(r) = \epsilon_i^p(r, t_{ub})$, and the entire shaft behaves elastically again. This approximation was discussed in detail in [38], where also an estimate for the occurring error was suggested: after the assumption of sudden unloading the equivalent stress σ_y , i.e., the difference of the extremal principal stresses according to Tresca's yield condition (which for a short interval of time exceeds the yield stress, thus slightly violating the yield condition), is calculated and compared with the yield stress. For a small difference of equivalent stress σ_y and yield stress σ_{th} , only a small error is to be expected; as it is shown in the next Chapter, this is the case for the present problem.

In this state, shaft behaves elastically in all radius of the shaft. However it should be noted that in the range of $0 < r < r_2^u$ predeformed elastic region governs and in the rest of the radial direction ($r_2^u < r < b$) only elastic region is the one where r_2^u is the radius of interface between plastic region II and elastic region at $t = t_{ub}$. Hence, for whole shaft, formulation of the predeformed elastic region can be taken into account with considering $\epsilon_i^{pr}(r) = \epsilon_i^{pI}(r, t_{ub})$ in $0 < r < r_1^u$, $\epsilon_i^{pr}(r) = \epsilon_i^{pII}(r, t_{ub})$ in $r_1^u < r < r_2^u$, and $\epsilon_i^{pr}(r) = 0$ in $r_2^u < r < b$ in which r_1^u is the interface radius between

plastic regions I and II at $t = t_{ub}$. Therefrom, to evaluate unknown constants, i.e., C_1^* , C_2^* and ϵ_0 , Eqs. (3.1–3.3) are used and following analytical expressions are obtained:

$$C_1^* = 0, \quad (5.23)$$

$$C_2^* = \frac{1}{2(1-\nu)b^2} \left[\frac{(3-5\nu)\rho\omega^2b^4}{8G(1+\nu)} - (1-2\nu)b^2 \int_0^b \frac{\epsilon_r^{pr} - \epsilon_\theta^{pr}}{\xi} d\xi \right. \\ \left. + \int_0^b \xi (\epsilon_r^{pr} + \epsilon_\theta^{pr}) d\xi + 2\alpha(1-3\nu) \int_0^b \xi T(\xi, t) d\xi \right], \quad (5.24)$$

$$\epsilon_0 = -\frac{\nu\rho\omega^2b^2}{4G(1+\nu)} - \frac{2}{b^2} \int_0^b \xi (\epsilon_r^{pr} + \epsilon_\theta^{pr}) d\xi + \frac{2\alpha}{b^2} \int_0^b \xi T(\xi, t) d\xi. \quad (5.25)$$

CHAPTER 6

RESULTS AND DISCUSSION

6.1 Non-Dimensional and Normalized Quantities

For the presentation of numerical results, it is customary to use formal non-dimensional and normalized parameters. They are listed below.

$$\begin{aligned} \text{radial coordinate : } x &= \frac{r}{b}, \\ \text{time : } \tau &= \frac{\kappa t}{b^2}, \\ \text{rotation speed : } \Omega^2 &= \frac{\rho \omega^2 b^2}{\sigma_0}, \\ \text{temperature dependence parameter : } \beta^* &= \beta T_m, \\ \text{temperature : } T^* &= \frac{T}{T_m}, \\ \text{stress : } \bar{\sigma}_i &= \frac{\sigma_i}{\sigma_0}, \\ \text{displacement : } \bar{u} &= \frac{uG}{b\sigma_0}, \\ \text{strain : } \bar{\epsilon}_i &= \frac{\epsilon_i G}{\sigma_0}. \end{aligned}$$

In addition, as a measure for the maximum surface temperature during the transient heating, the parameter q is introduced. It is defined as

$$q = \frac{\alpha T_m G}{\sigma_0}. \quad (6.1)$$

If the governing equations are rewritten in terms of these non-dimensional and normalized variables, dimensionless forms of integration constants are obtained. They

are:

$$\bar{C}_1 = \frac{C_1 G}{b^2 \sigma_0}, \quad (6.2)$$

$$\bar{C}_2 = \frac{C_2 G}{\sigma_0}, \quad (6.3)$$

$$\bar{C}_3 = \frac{C_3}{\sigma_0}, \quad (6.4)$$

$$\bar{C}_4 = \frac{C_4 G}{b^2 \sigma_0}, \quad (6.5)$$

$$\bar{C}_5 = \frac{C_5 b^{-1+M} G}{\sigma_0}, \quad (6.6)$$

$$\bar{C}_6 = \frac{C_6 b^{-1-M} G}{\sigma_0}. \quad (6.7)$$

Note that the term used in Eq. (3.10) may be normalized as

$$\bar{\gamma}_n = b \gamma_n.$$

Finally, by using Eq. (5.5), non-dimensional elastic limit rotation speed is expressed as

$$\Omega_e^i = \frac{2\sqrt{2(1-\nu)}}{\sqrt{3-4\nu}}. \quad (6.8)$$

6.2 Numerical Results

Numerical results are obtained by the calculation of unknown constants, analytical and numerical integrals and Bessel and hypergeometric functions in purely elastic, elastic-plastic and unloaded states. These calculations are performed by executing Fortran programs. Description of these programs are given in Appendix A and the program codes are presented in Appendices B–D.

The temperature cycle introduced in Figure 3.2 is plotted in Figure 6.1 for the non-dimensional time parameters $\tau_t = 1.2$ and $\tau_c = 0.3$. As seen in the figure, the outer surface is heated until $\tau = \tau_t = 1.2$. Hence, the outer surface temperature reaches maximum surface temperature and it is kept constant at that one until $\tau = \tau_t + \tau_c = 1.5$. Then, cooling starts and it ends at $\tau = 2\tau_t + \tau_c = 2.7$. Therefore, the surface temperature drops back to the reference temperature and it remains there for $\tau \geq 2.7$.

The evolution of the temperature field with time for the described temperature cycle is shown in Figures 6.2–6.6. The temperature field throughout the radial coordinate of

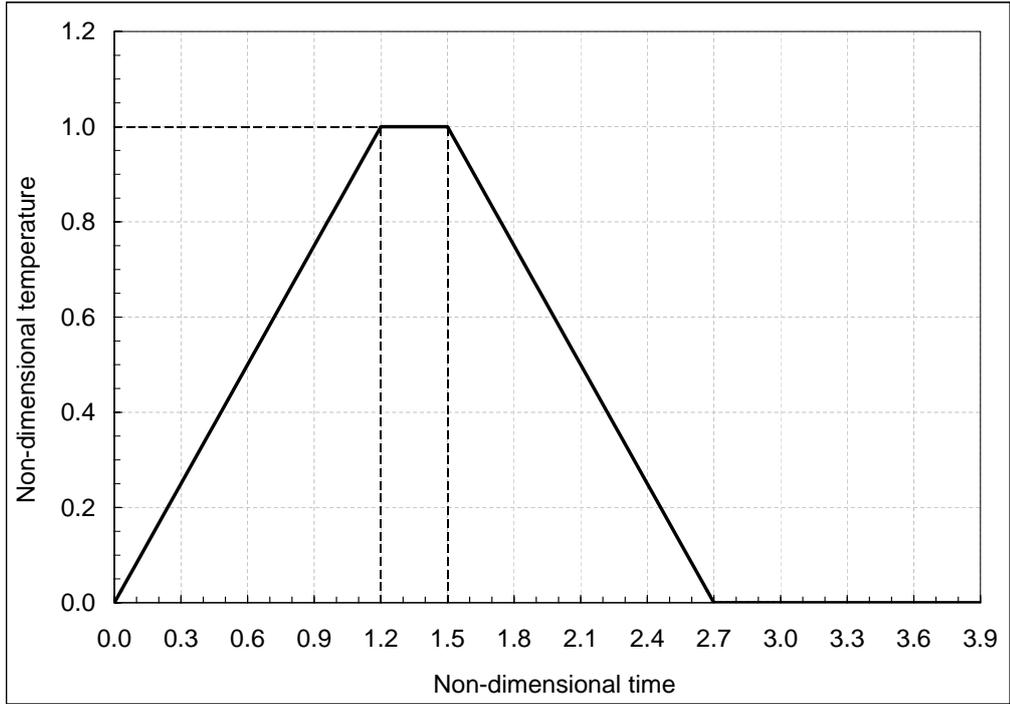

Figure 6.1: Prescribed surface temperature of the shaft ($x = 1$)

the shaft during heating $\tau \leq 1.2$ (see Figure 6.1) at different times is shown in Figure 6.2. In this heating region, a positive temperature gradient is observed between the outer surface and the center of the shaft. Figure 6.3 shows the evolution of temperature field in the time interval $1.2 \leq \tau \leq 1.5$. One observes that only after the onset of cooling at $\tau = 1.5$ does the temperature in the inner parts of the shaft reach its maximum. Additionally, it should be noted that at $\tau = 1.5$, the temperature distribution is very close to isothermal case as difference of temperature between center and outer surface temperatures is very small.

In the Figure 6.4, temperature distribution in the shaft at the cooling time interval, i.e., $1.5 \leq \tau \leq 2.7$, is presented. At the end of this time period, temperature cycle is completed and the outer surface temperature returns to the reference temperature. After this moment, the outer surface stays at the reference temperature and hence isothermal shaft behavior is obtained eventually. Figures 6.5 and 6.6 put on view the evolution of the temperature field for $\tau > 2.7$. With increasing time, the entire shaft cools down and an isothermal behavior is observed. Figure 6.6 is given in a small scale

to emphasize the cases when the whole shaft gets closer to the isothermal case.

During heating, the temperature difference between the outer surface and the center of the shaft changes. This situation is depicted in Figure 6.7. This figure is useful to explain the behavior of the thermal loading. For example; positive temperature gradient is observed until $\tau = 1.5$, but then negative temperature gradient emerges for $\tau > 1.5$. The effect of these two types of thermal loading on the behavior of the deformation is expected to be different.

Table 6.1: Calculated constants of \bar{C}_2 and $\bar{\epsilon}_0$ at different rotations speeds in purely elastic state

Rotation Speed (Ω)	\bar{C}_2	$\bar{\epsilon}_0$
0.4410 ($0.25 \times \Omega_e^i$)	2.003205×10^{-2}	-1.121795×10^{-2}
0.8819 ($0.5 \times \Omega_e^i$)	8.012821×10^{-2}	-4.487180×10^{-2}
1.3229 ($0.75 \times \Omega_e^i$)	0.180289	-0.100962
1.5875 ($0.9 \times \Omega_e^i$)	0.259615	-0.145385

As mentioned earlier, before the temperature cycle is applied, the shaft is rotated up to a certain rotation speed, which is below the elastic limit for isothermal case Ω_e^i . In this investigation, the maximum rotation speed is selected as 90 % of elastic limit rotation speed for isothermal shaft. By choosing $\nu = 0.3$, the maximum rotation speed is calculated as 1.5875 with help of Eq. (6.8). Other parameter values for the selected material are $q = 0.6$ and $\beta^* = 0.2$. Change of stresses and displacement distributions with increasing rotation speed for $\Omega \leq 1.5875$ are plotted in Figures 6.8–6.11. It should be noted that the shaft is only under centrifugal force because of rotation and it has not been subjected to any thermal load yet. In Figure 6.8, radial stress, in Figure 6.9 circumferential stress, in Figure 6.10 axial stress and in Figure 6.11 radial displacement distributions are plotted for different rotation speeds. For these speeds, unknown constants are calculated by using Eqs. (5.2) and (5.3) and given in table 6.1. Finally, $\Omega = 0.9 \times \Omega_e^i = 1.5875$ is selected as maximum rotation speed in this study and distributions of stresses, displacement and ratio of equivalent stress and yield stress $\bar{\sigma}_y/\bar{\sigma}_{th}$ under this rotation speed are also plotted in Figure 6.12. As seen in the figure, the ratio of $\bar{\sigma}_y/\bar{\sigma}_{th}$ is less than 1 since yielding does not occur yet.

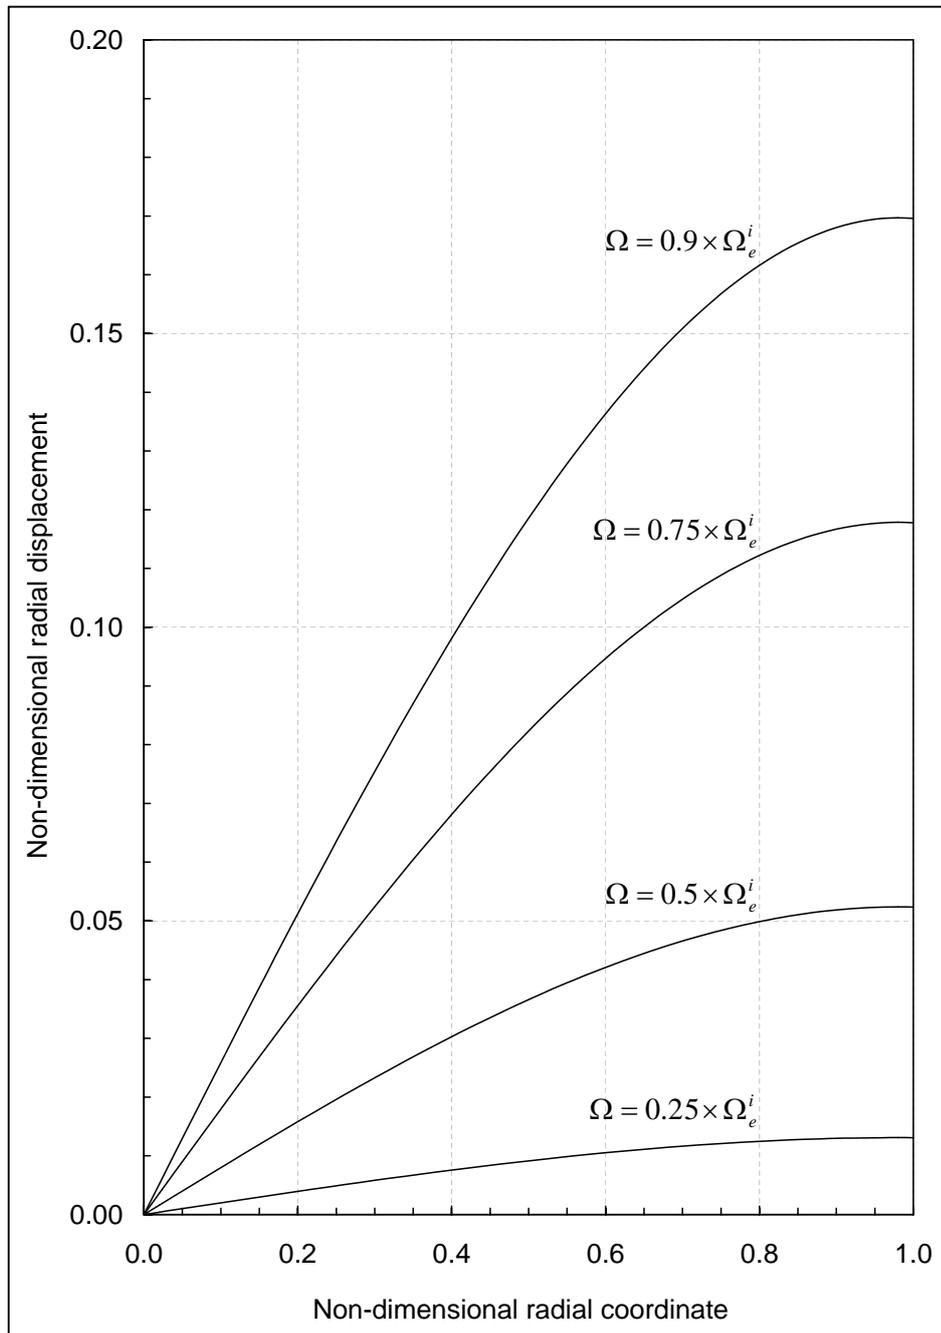

Figure 6.11: Radial displacement distribution in the shaft with increasing rotation speed

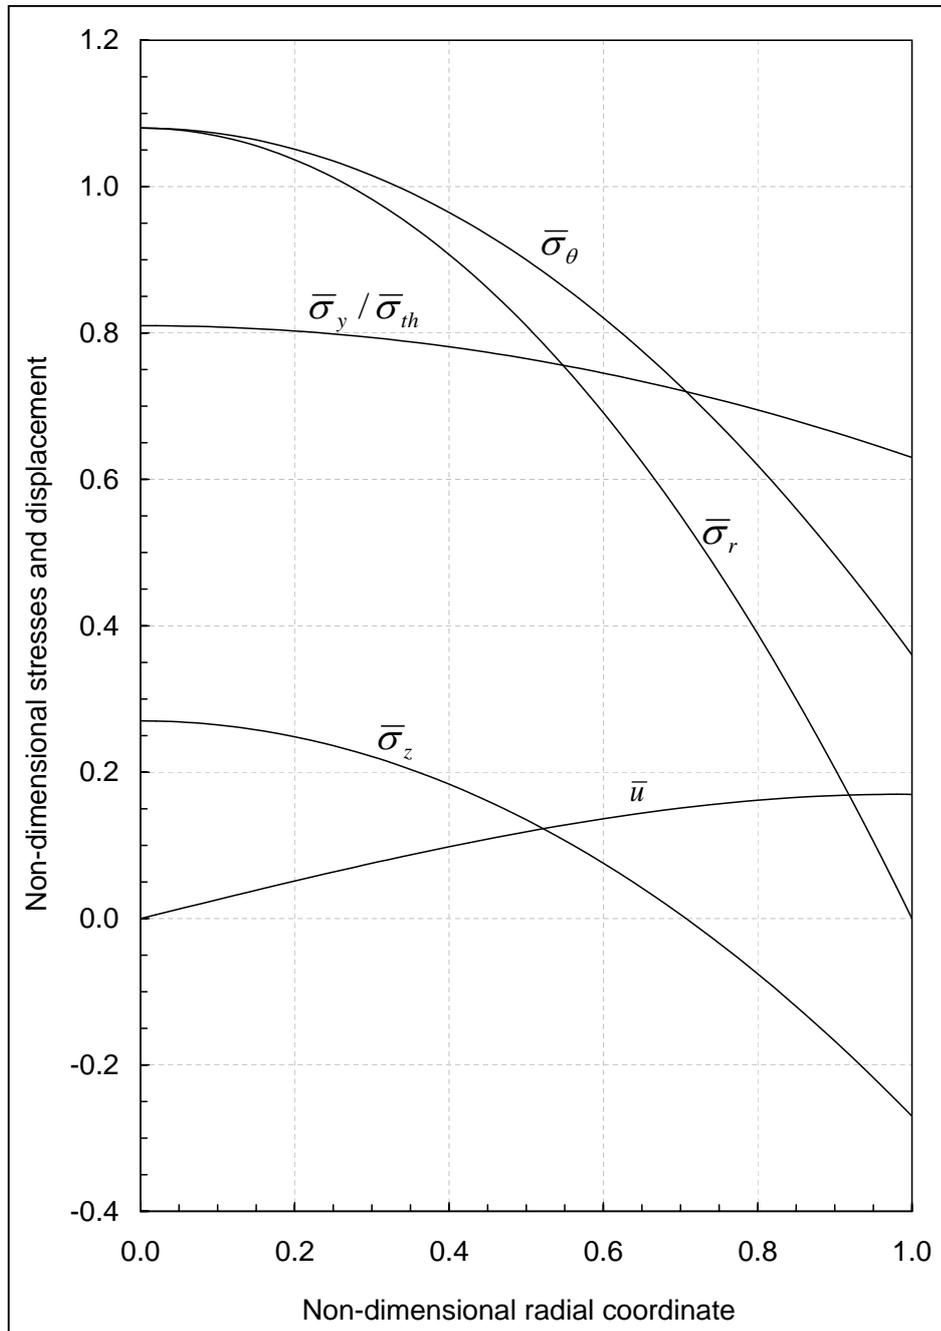

Figure 6.12: Stresses and radial displacement distributions in purely elastic state under $\Omega = 0.9 \times \Omega_e^i = 1.5875$

In the following calculations, rotation speed is fixed at $\Omega = 0.9 \times \Omega_e^i = 1.5875$ and temperature cycle, which is described in Figure 6.1, is started to be applied. The next step is to find the yielding time and the location where it initially starts. For this reason, time is slowly increased in the temperature cycle and it is searched whether the condition of $\sigma_y = \sigma_{th}$ is reached. In Figure 6.13, distribution of $\bar{\sigma}_y/\bar{\sigma}_{th}$ along the radial direction at different times is presented. As seen in the figure, at $\tau = 0$, which is the beginning of the temperature cycle, this ratio is less than 1. As time passes, the ratio decreases until around $\tau = 0.37$. Then the ratio starts to increase dramatically. When time reaches to $\tau = \tau_p = 1.5519$, which is shortly after the beginning of the cooling time ($\tau = \tau_t + \tau_c = 1.5$), $\bar{\sigma}_y/\bar{\sigma}_{th}$ becomes equal to 1 at $x = 0$. It is observed that the center of the shaft is a critical location for yielding. The evolution of the ratio $\bar{\sigma}_y/\bar{\sigma}_{th}$ with time at $x = 0$ is plotted in Figure 6.14. As seen in this figure, the ratio decreases in the early stages until around $\tau = 0.37$ as observed in Figure 6.13. One observes that only after the onset of cooling at $\tau = 1.5$ the temperature of the inner parts of the shaft reaches its maximum. The corresponding reduction of the yield stress σ_{th} leads to plasticization, which starts at the center. Hence, the last two figures prove that plastic deformation emerges firstly at $\tau = \tau_p = 1.5519$ and on $x = 0$.

Table 6.2: Calculated constants of \bar{C}_2 and $\bar{\epsilon}_0$ versus time in purely elastic state

Time (τ)	\bar{C}_2	$\bar{\epsilon}_0$
0.3	0.266619	-4.733532×10^{-2}
1.2	0.298012	0.392173
1.35	0.300679	0.429501
1.5	0.301720	0.444076
1.5519 (τ_p)	0.301329	0.438607

Elastic stresses and displacement for different time values prior to yielding ($\tau < 1.5519$) are calculated after the determination of the corresponding integration constants. These constants are presented in table 6.2. In Figures from 6.15 to 6.18, radial stress, circumferential stress, axial stress and radial displacement distributions at different time steps in $\tau < 1.5519$ are presented, respectively. Finally, distributions of stresses and radial displacement at $\tau = \tau_p = 1.5519$ is shown all together in Figure 6.19. It should be noted again that this figure is drawn at a time when yielding starts. Hence, formulation of elastic-plastic state is used for $\tau > 1.5519$ until unloaded state.

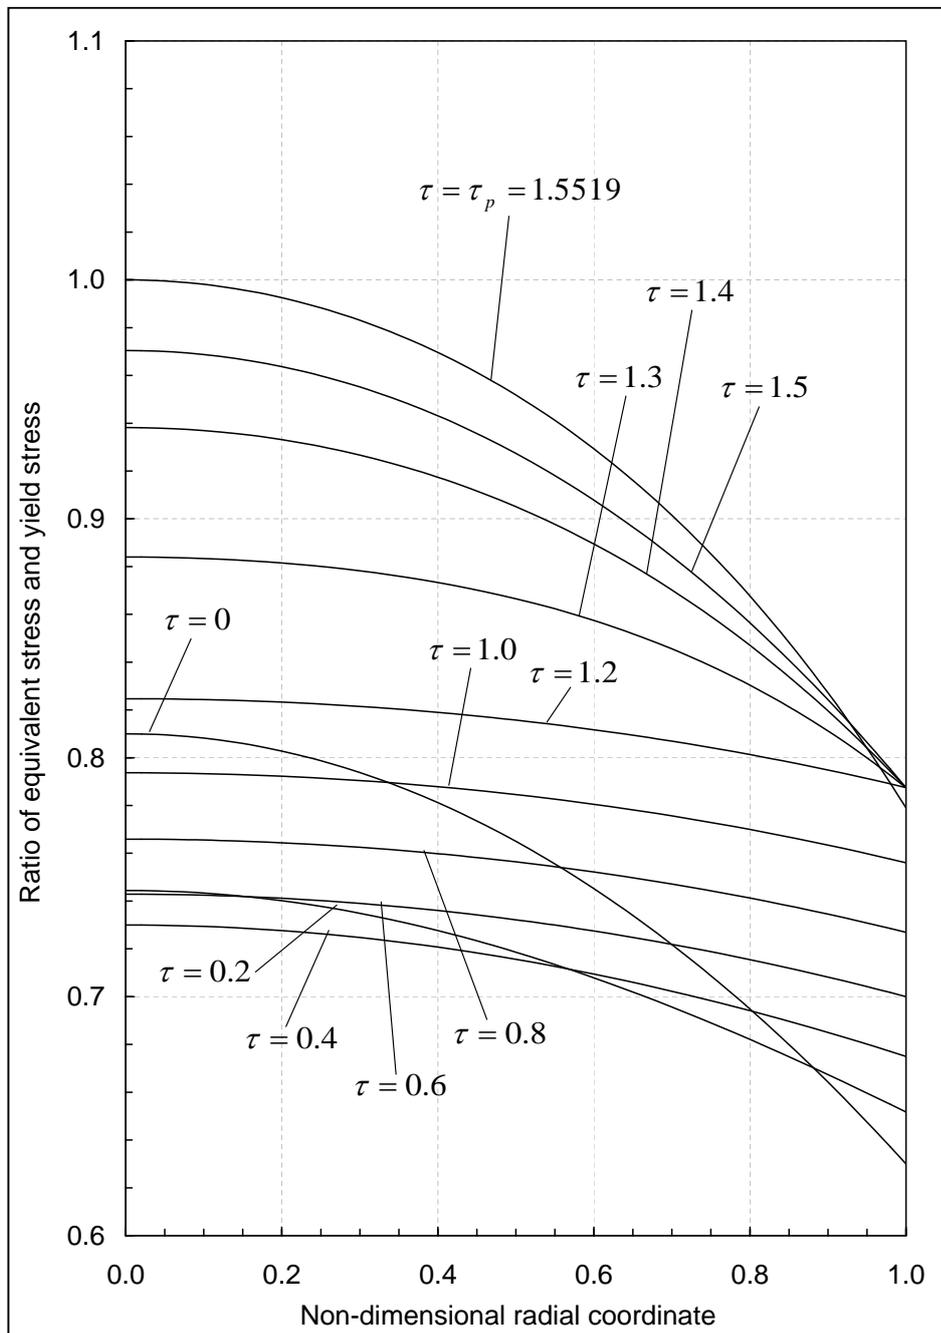

Figure 6.13: Ratio of equivalent and yield stresses at different time until plastic flow

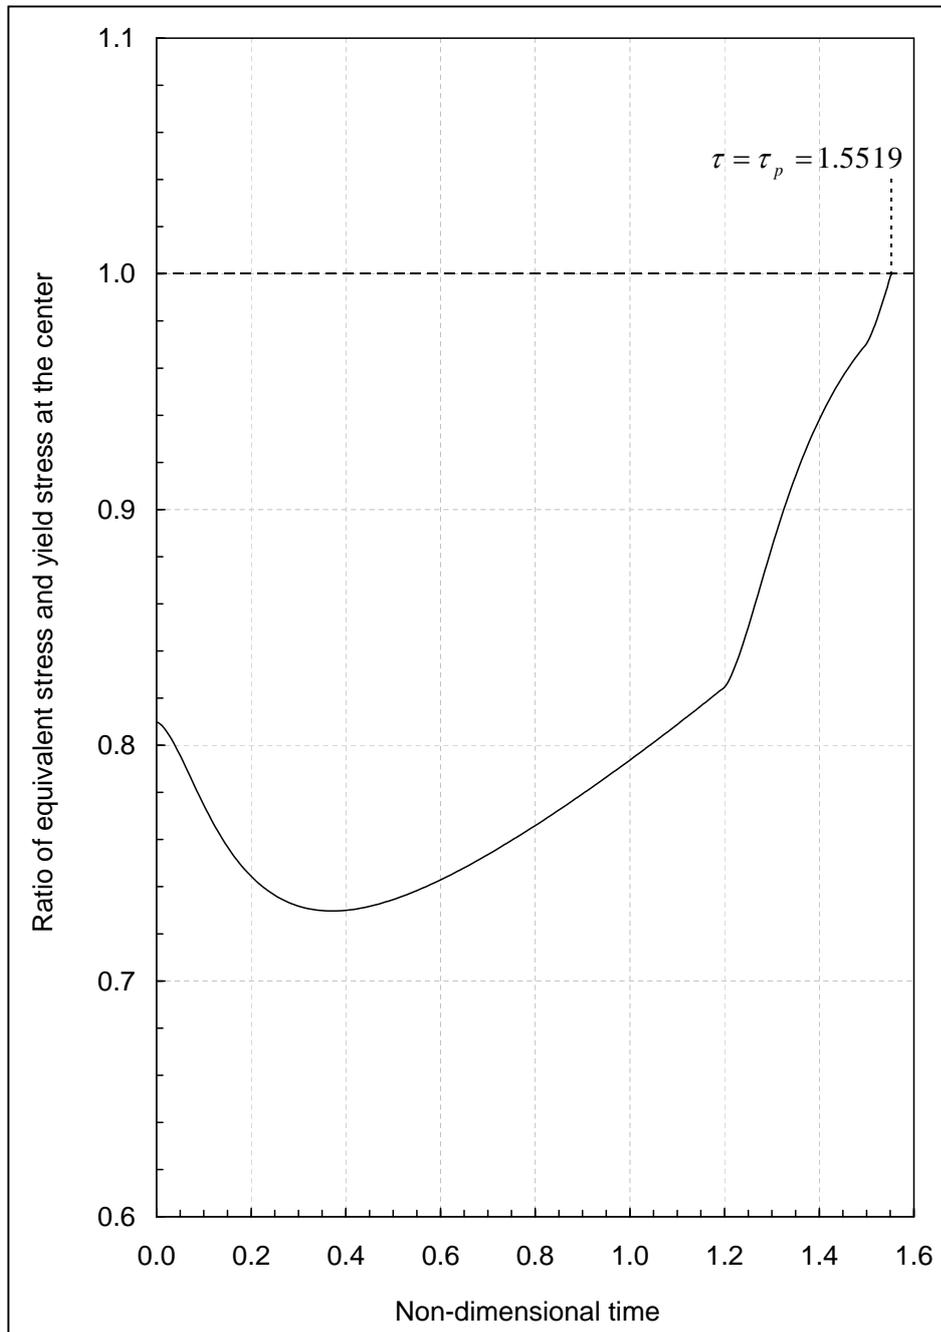

Figure 6.14: Change of ratio of equivalent and yield stresses with time until plastic flow at the center

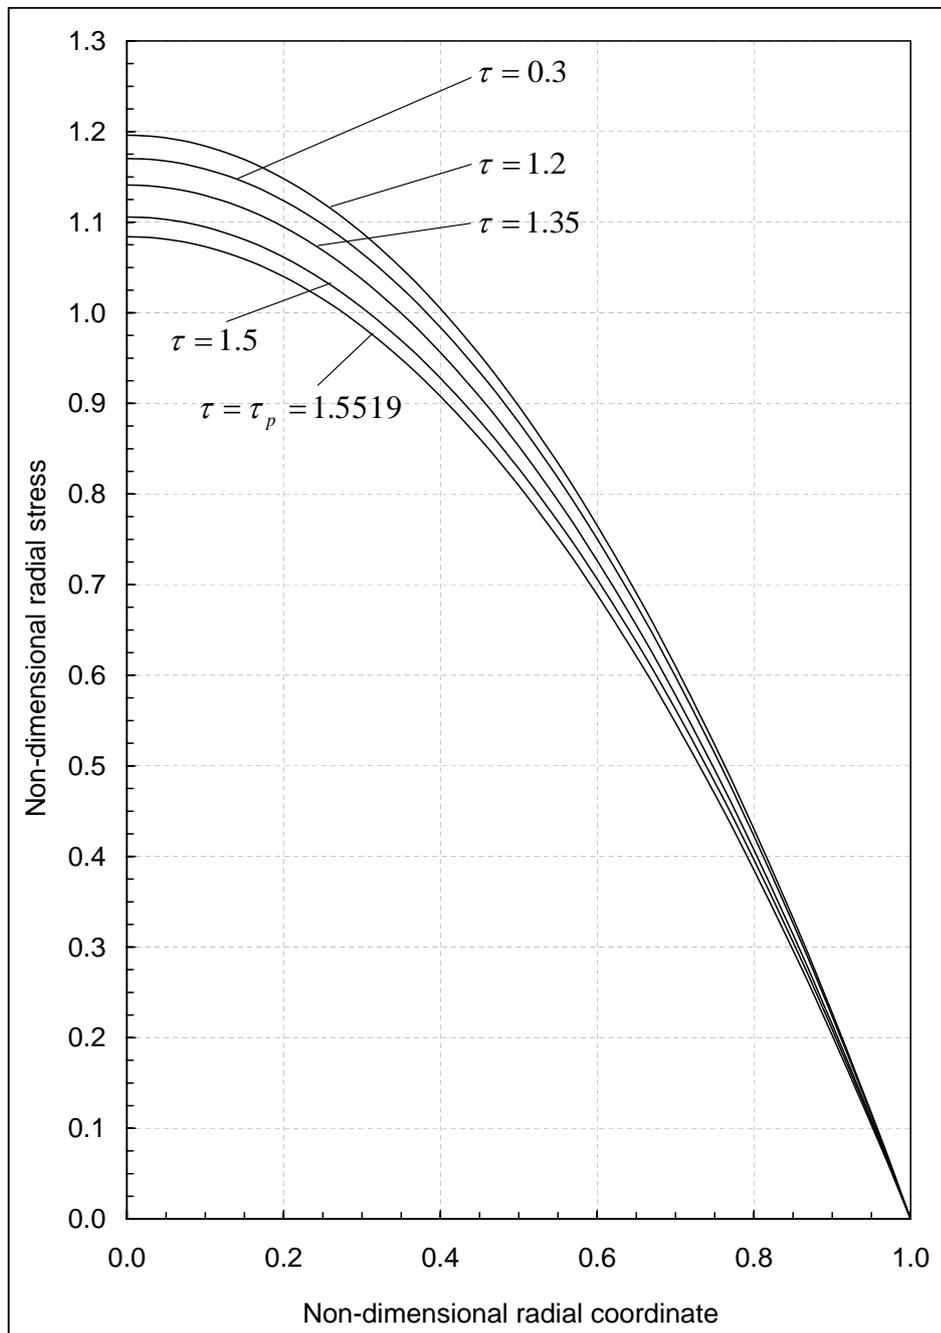

Figure 6.15: Radial stress distribution at different time steps in purely elastic state

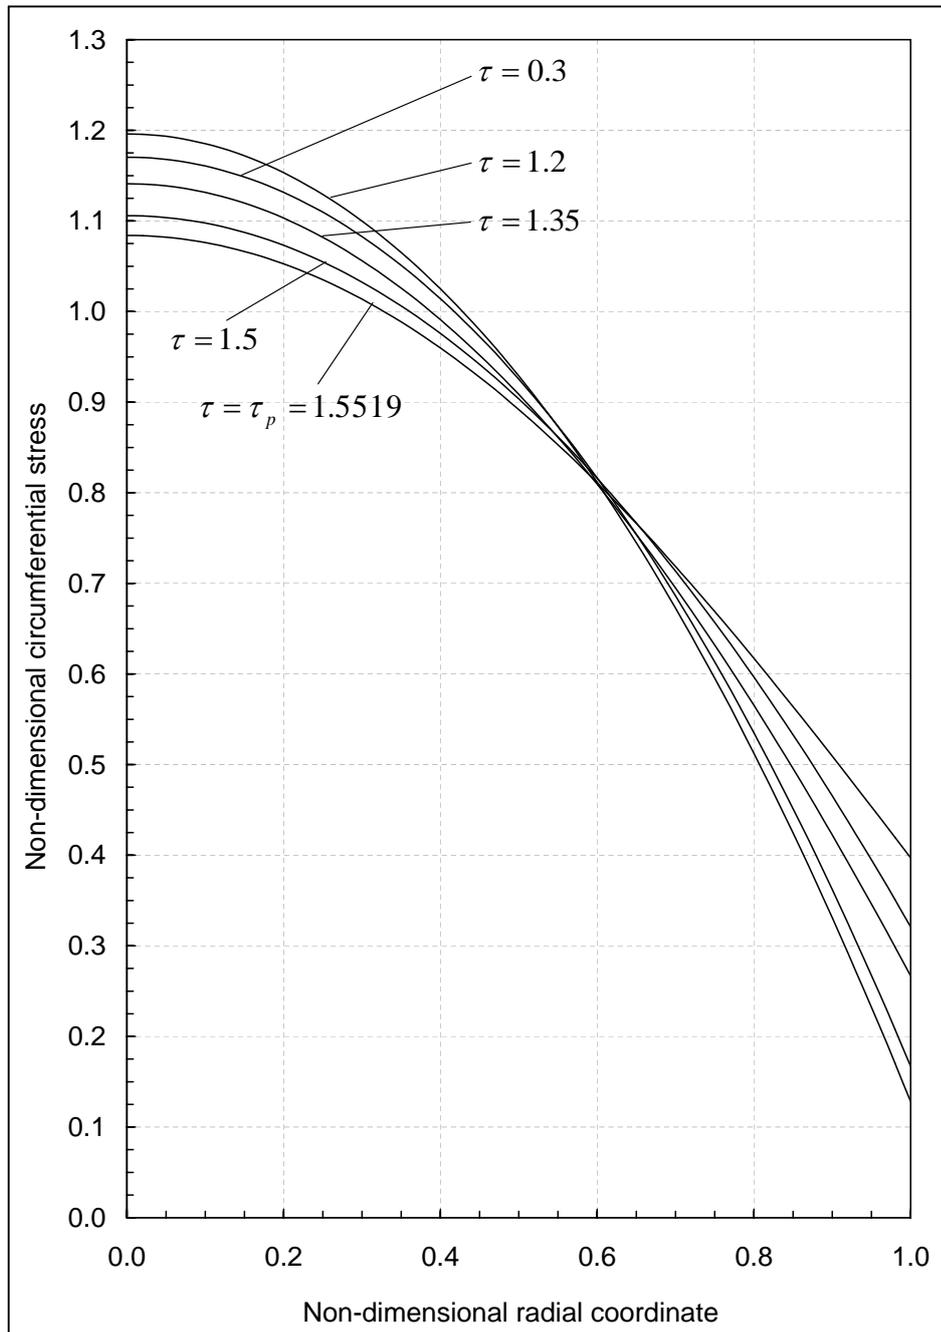

Figure 6.16: Circumferential stress distribution at different time steps in purely elastic state

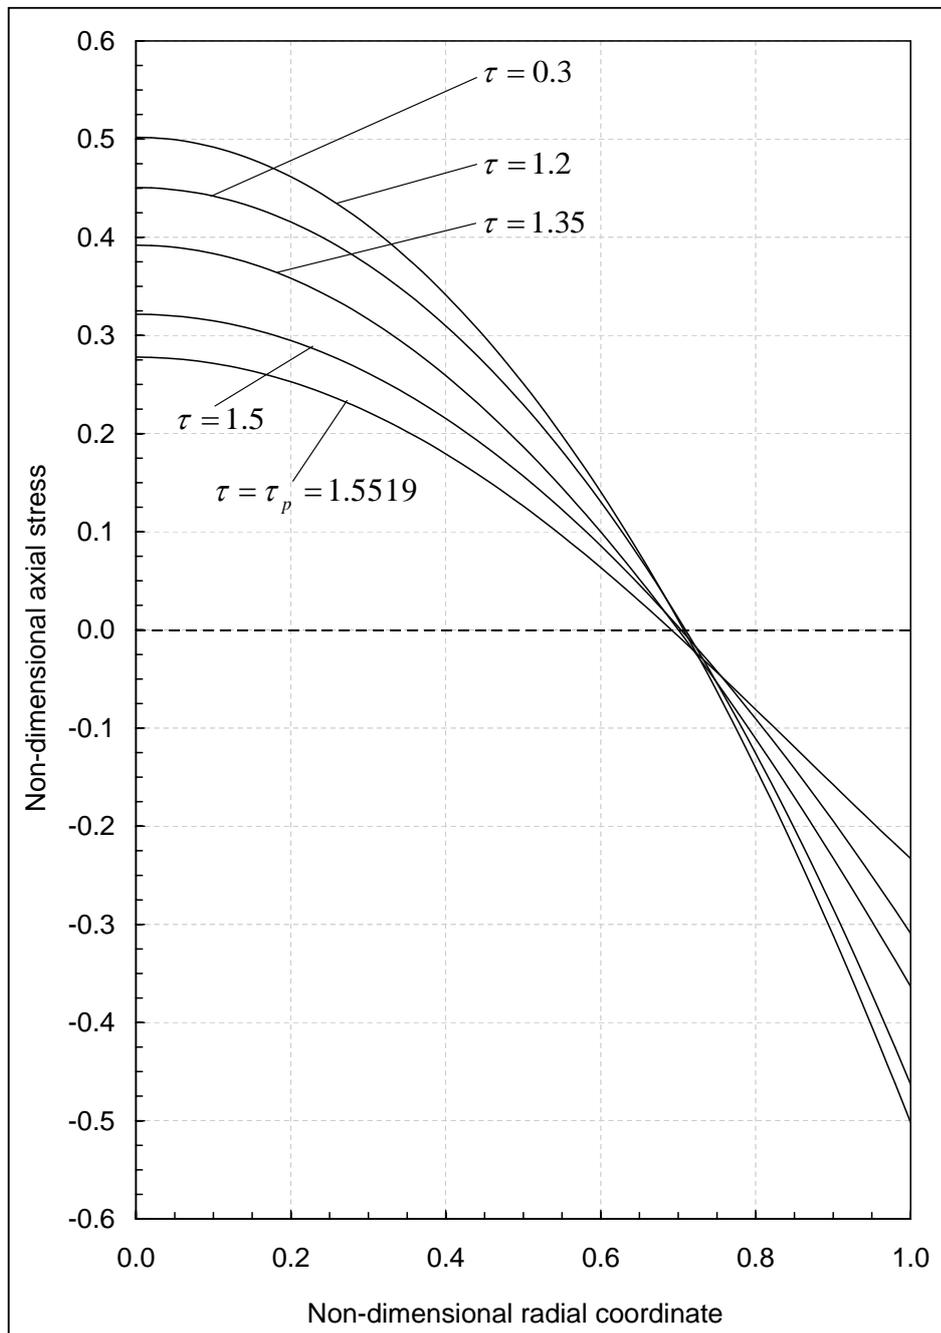

Figure 6.17: Axial stress distribution at different time steps in purely elastic state

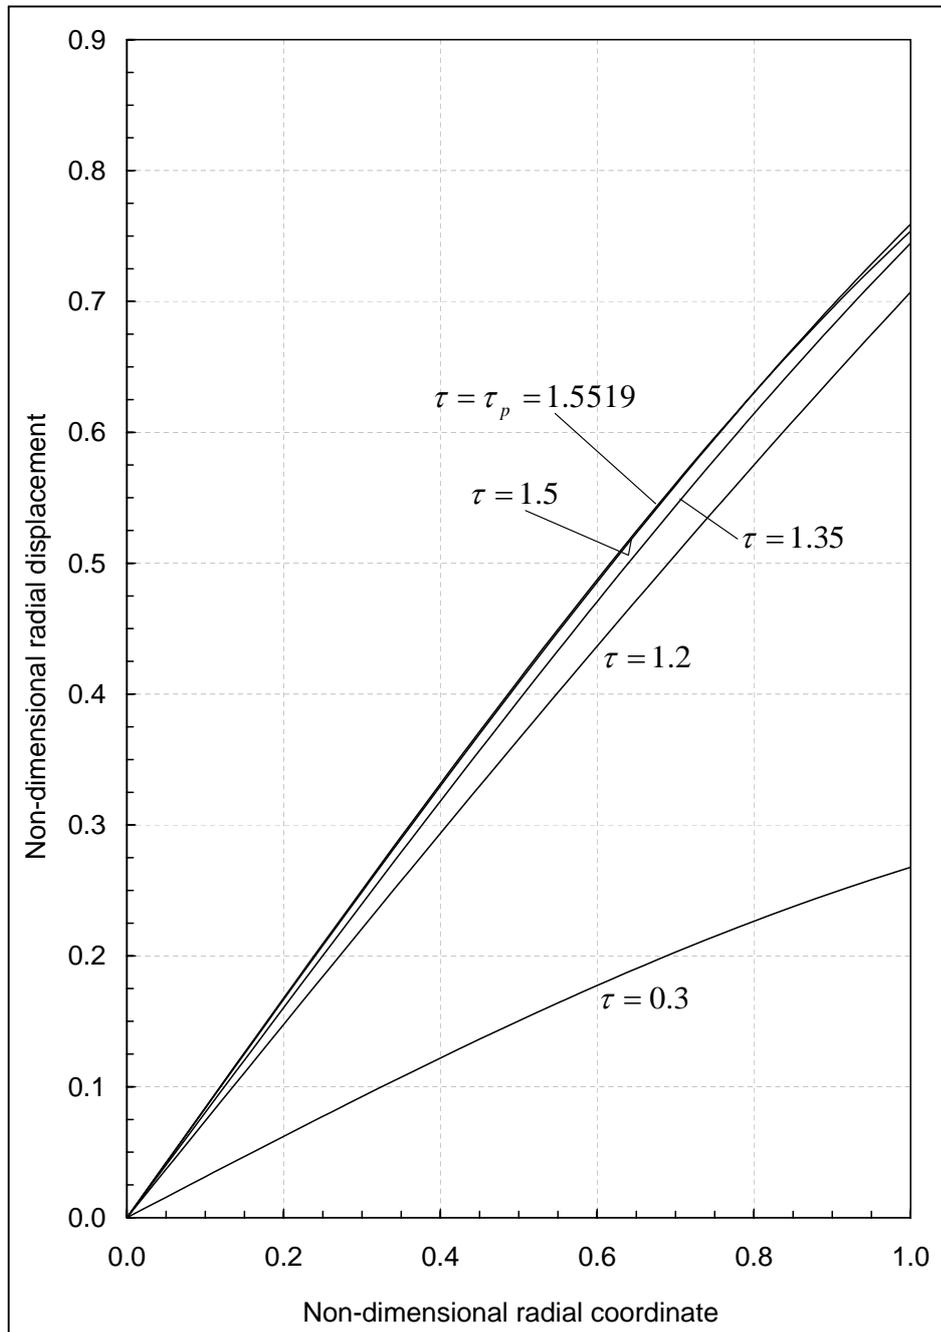

Figure 6.18: Radial displacement distribution at different time steps in purely elastic state

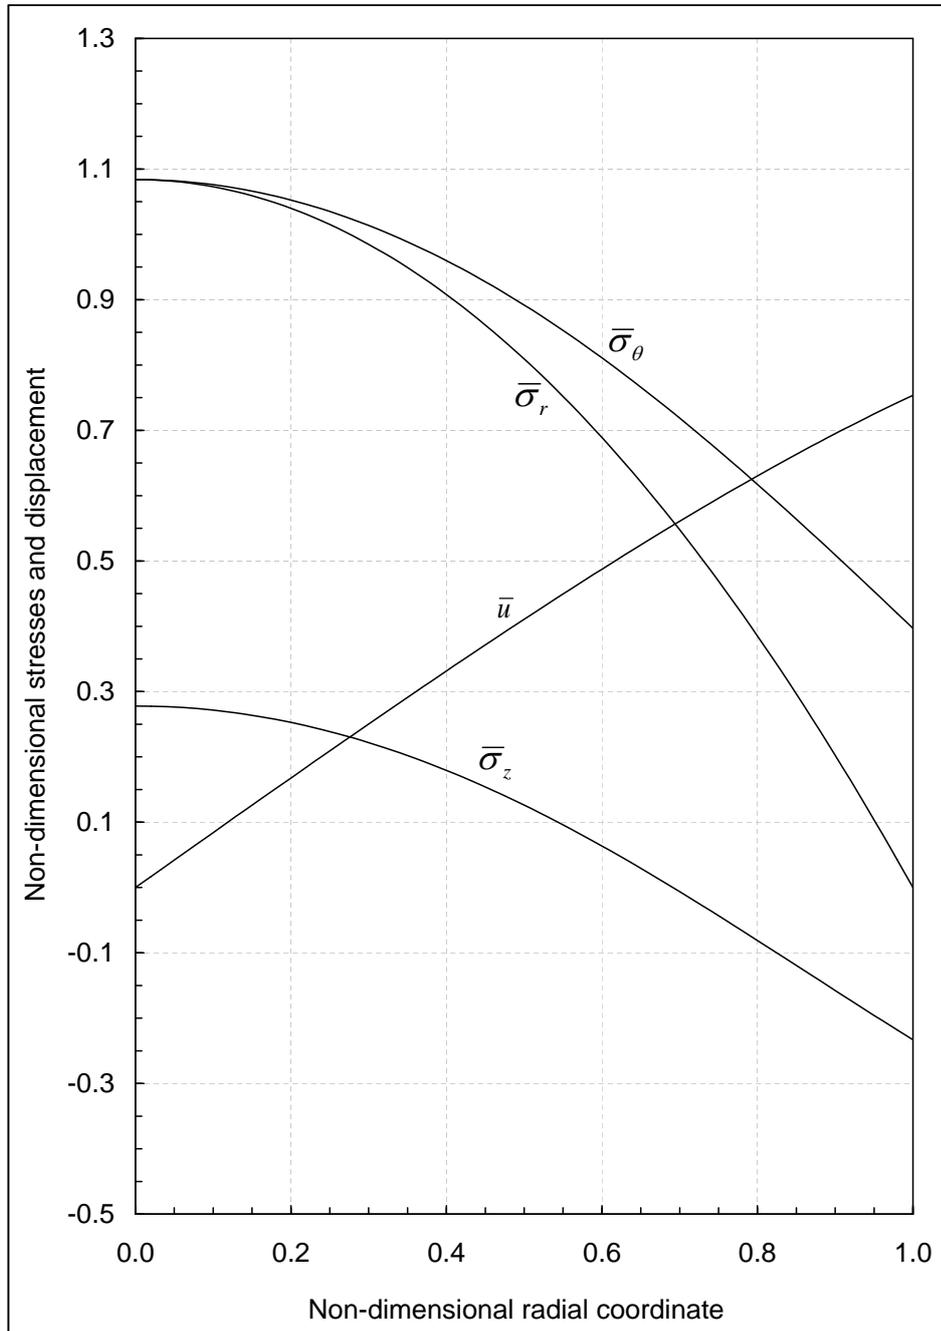

Figure 6.19: Stresses and radial displacement distributions in purely elastic state at $\tau = \tau_p = 1.5519$

As stated earlier, elastic-plastic state of stress is confined in the time interval $\tau_p < \tau < \tau_{ub}$ with onset of plasticization time τ_p and unloading bounding time τ_{ub} being critical time intervals to be determined. In order to determine τ_{ub} , the condition that is described in Eq. (5.21) is used. Evolution of plastic circumferential strain component with respect to time is observed. In the shaft, there are three critical locations where unloading may commence. These are center of the shaft $x = 0$, interface radius between two plastic regions $x = x_1$, and interface radius between plastic region II and elastic region $x = x_2$. Here, it should be noted that x_1 and x_2 are functions of time. Evolutions of plastic circumferential strain component at $x = 0$ and $x = x_1(\tau)$ are plotted in Figure 6.20. Additionally, derivative of plastic circumferential strain with respect to time is calculated by using forward difference as

$$\frac{d\epsilon_{\theta}^p}{d\tau} = \frac{\epsilon_{\theta}^p(\tau + \Delta\tau) - \epsilon_{\theta}^p(\tau)}{\Delta\tau}, \quad (6.9)$$

and plotted in Figure 6.21 using time increments of $\Delta\tau = 0.005$. As seen in these two figures, plastic circumferential strain component increase first, then rate of the increase slows down with time. For $x = x_1$, increase in the strain ceases at $\tau = \tau_{ub}|_{x=x_1} = 1.8454$, i.e., when the condition of (5.21) is satisfied. This time may be considered as a possible starting time of unloaded state according to interface radius between two plastic regions. However, unloading starts at the center at $\tau = \tau_{ub}|_{x=0} = 1.8469$ as followed in these figures. This shows that x_1 is more critical radial coordinate than the center of the shaft since unloading emerges earlier. Furthermore, the small time difference of τ_{ub} between these two points proves that movement of unloading from interface radius x_1 to the center is very fast.

On the other hand, another critical radial coordinate that is $x = x_2$ should be examined for unloading condition. At this interface radius, plastic circumferential strain is always zero because this radial coordinate is adjacent to the elastic region. Hence, it is not possible to investigate the behavior of the plastic strains at this coordinate like at $x = 0$ or $x = x_1$. However, evolution of interface radius x_2 with time gives some hints to evaluate the behavior of the plastic strains around there. Evolution of $x_2(\tau)$ with time is plotted in Figure 6.22. Additionally, evolution of change in x_2 with time is obtained by forward difference, which is similar to the Eq. (6.9)

$$\frac{dx_2(\tau)}{d\tau} = \frac{x_2(\tau + \Delta\tau) - x_2(\tau)}{\Delta\tau}, \quad (6.10)$$

and plotted in Figure 6.23 by choosing $\Delta\tau = 0.002$. These two figures show that when time reaches $\tau = 1.7882$, expansion of x_2 stops all of a sudden. This situation is quite interesting since plastic region always moves into elastic region during loading. Because of the termination in the expansion of plastic region II, plastic strains does not increase at any radial coordinates beyond x_2 . Hence, condition of (5.21) is satisfied at $\tau = 1.7882$ and on $x = 0.5707$. Furthermore, this time value is earlier than those for $x = 0$ and $x = x_1$. Thus, we can discuss that unloading emerges at $\tau = \tau_{ub} = 1.7882$ on $x = 0.5707$ and moves into plastic regions. Therefore, we have obtained the time limits of elastic-plastic state.

Table 6.3: Calculated constants in elastic-plastic state at different time values

Time (τ)	\bar{C}_1	\bar{C}_2	\bar{C}_3	\bar{C}_4	\bar{C}_5
1.5519 (τ_p)	0	0.301329	1.083954	0	0
1.57	1.556682×10^{-5}	0.301106	1.077291	0	4.246629×10^{-3}

1.66	2.245565×10^{-5}	0.406789
1.72	3.529008×10^{-5}	0.38360
1.7882 (τ_{ub})	4.223217×10^{-5}	0.355186

Numerical results for the elastic-plastic state in time interval $\tau_p < \tau < \tau_{ub}$ are presented in Figures 6.24–6.34. In Figure 6.24, stresses, radial displacement and the ratio of equivalent and yield stresses are plotted at $\tau = \tau_p = 1.5519$, which is the upper time limit of the purely elastic state and the lower time limit of the elastic-plastic state. In the figure, while dots represent the results that are obtained with the formulation of the purely elastic state, solid lines represent those of the elastic-plastic state. As seen in the figure, these two results perfectly fit each other and this verifies that formulations of the both states are correct. Thereafter, time instant is selected as $\tau = 1.57$, $\tau = 1.6$, $\tau = 1.66$, $\tau = 1.72$ and $\tau = \tau_{ub} = 1.7882$ to plot corresponding distributions of stresses and displacement in Figures 6.25–6.29, respectively. Similarly,

at these time instants, plastic strains are presented in Figures 6.30–6.34. The plastic strains at $\tau = \tau_{ub} = 1.7882$ are permanent plastic strains which will be used in the unloaded state and are also presented in tabular form in Appendix D.2. Additionally, the unknown integration constants that are calculated in elastic-plastic state are given in table 6.3.

Evolution of the border radii in $\tau_p < \tau < \tau_{ub}$ gives enough information about the elastic-plastic behavior of the material under loading. This evolution with all regions and critical time values, i.e., τ_p and τ_{ub} , can be seen in Figure 6.35. This figure shows that, at $\tau = \tau_p = 1.5519$ plastic regions I and II emerge simultaneously and spread out (compare [12]). Up to $\tau = \tau_{ub}$, the shaft consists of plastic region I at inner part, plastic region II at the middle and elastic region at outer part. However, the expansion of the plastic zone comes soon to an end, and at $\tau = \tau_{ub} = 1.7882$ the plastic-elastic border radius x_2 attains a stationary value as explained with Figures 6.22 and 6.23. At $\tau = \tau_{ub} = 1.7882$, plastic strains that are seen in Figure 6.34, are frozen and the quick expansion of an unloaded region is approximated by the assumption of sudden unloading (indicated by the dashed line in Figure 6.35). Here x_u separates plastic regions and predeformed elastic region. That is, for $\tau > \tau_{ub}$, the shaft consists of predeformed elastic region, in the range $0 \leq x \leq x_2^u (= 0.5707)$ and elastic region in the range $x_2^u \leq x \leq 1$, and unloaded state will be valid in the whole shaft.

As discussed above, sudden unloading is approximated in this study. Error between this approximation and exact unloading is negligibly small as shown in [38]. Furthermore, to estimate error thus introduced, Figure 6.36 depicts the ratio of the equivalent stress $\bar{\sigma}_y$ and the yield stress $\bar{\sigma}_{th}$ versus time for three different radii, i.e., $x = 0$, $x = 0.1$ and $x = x_1(\tau_{ub}) = 0.2324$. One observes that the maximum violation of the yield condition occurs at the center, but it is only about 0.3 %. Hence, one reasonably may conclude that the stress distribution thus obtained is a very good approximation of the true stress distribution.

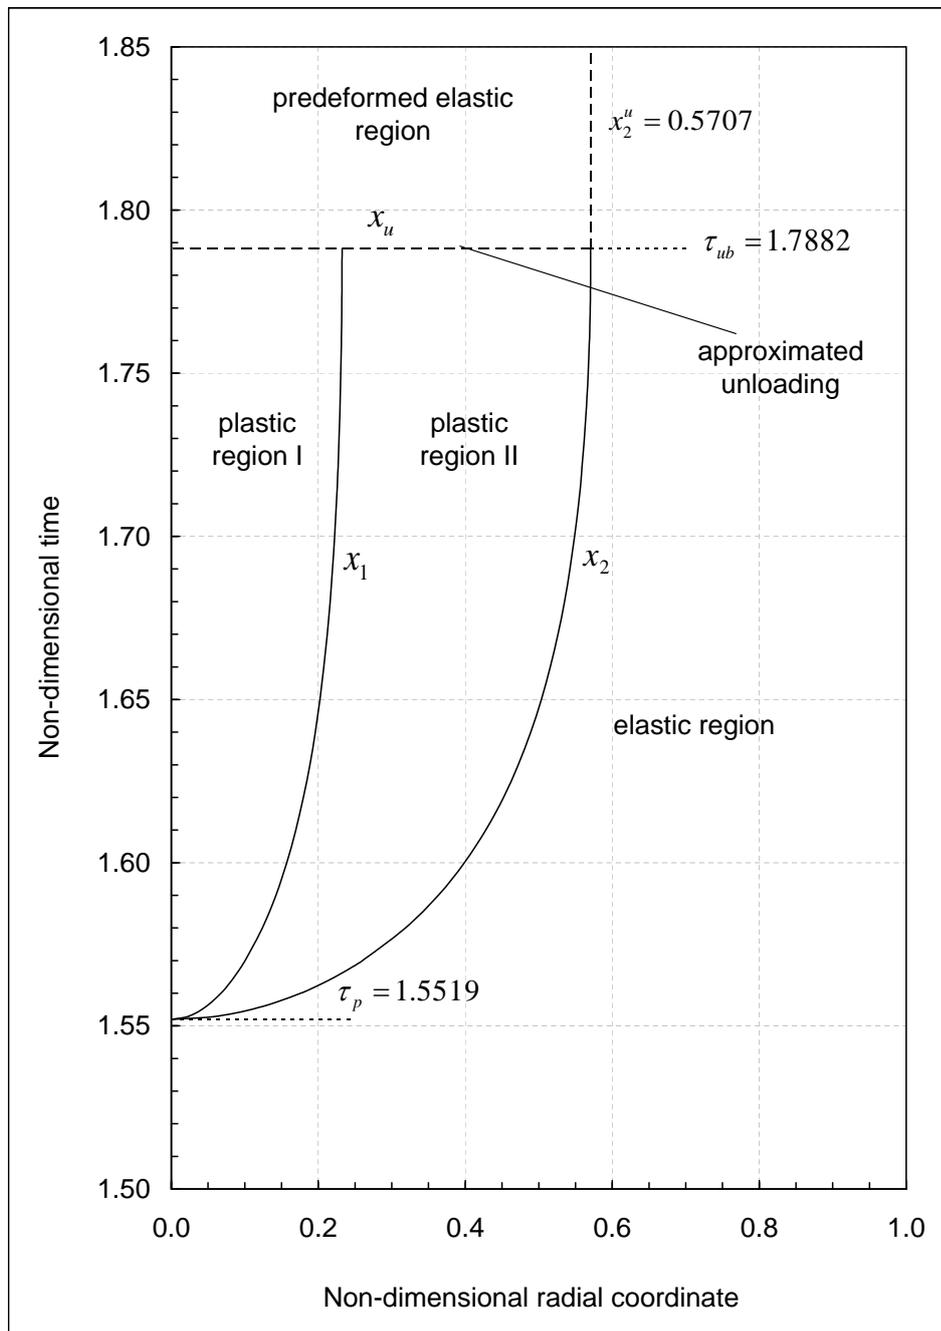

Figure 6.35: Evolution of plastic regions with time

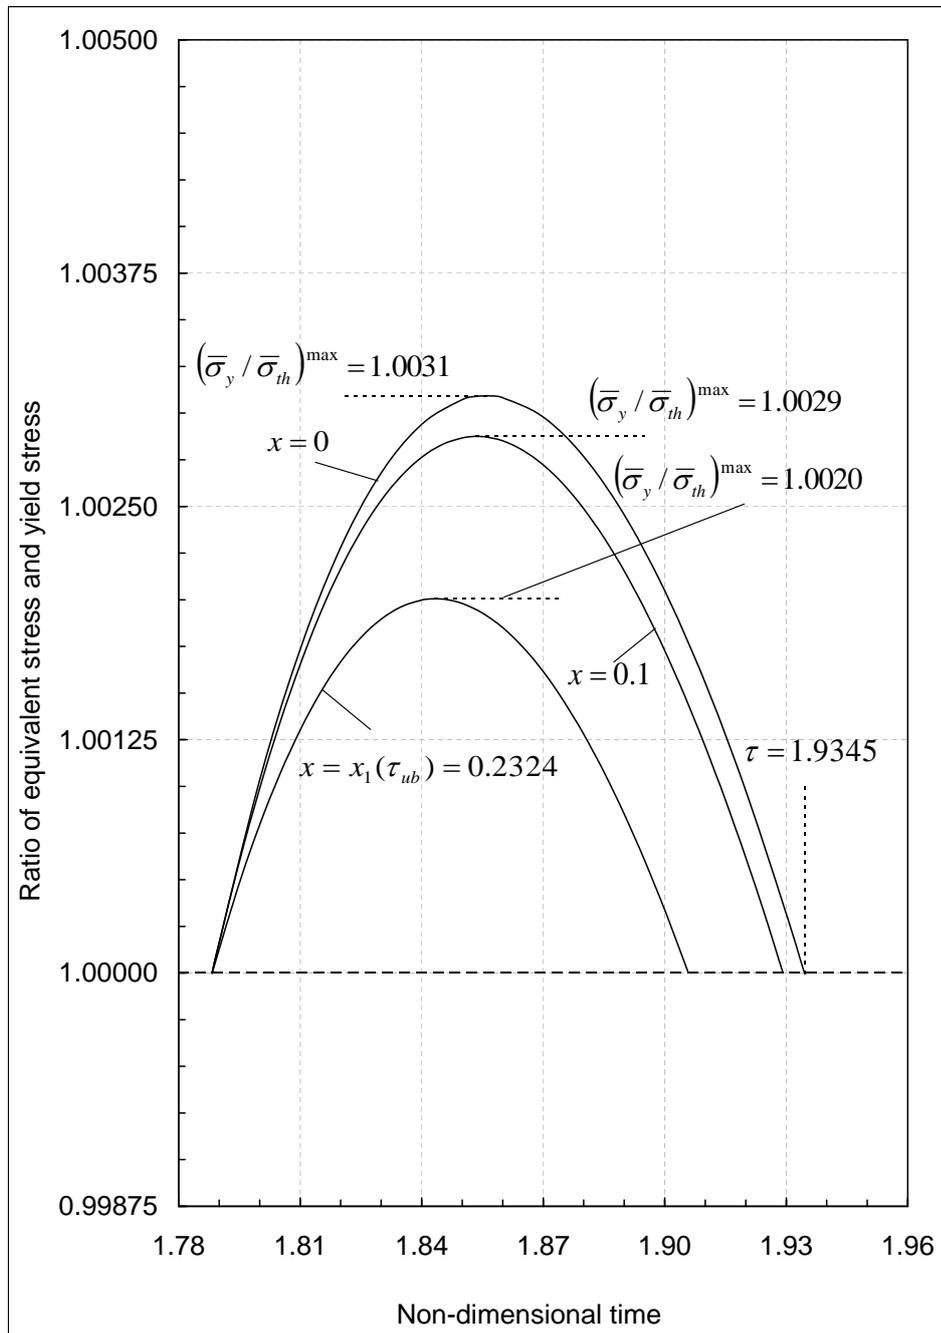

Figure 6.36: Evolution of the ratio of equivalent and yield stresses with time for three different radii after assumed sudden unloading

To observe stresses and displacement in unloaded state at $1.7882 < \tau < 2.7$, Figures from 6.37 to 6.42 are plotted. Response variables are calculated at the upper time limit of elastic-plastic state and at the beginning time of the unloaded state, $\tau = \tau_{ub} = 1.7882$, and drawn in Figure 6.37. In the figure, dots represents the results of the elastic-plastic state, and solid lines are those of unloaded state. As seen in the figure, fairly good agreement between two results is obtained. This verifies that the formulations of the both states are correct. Moreover, in Figure 6.38, time is selected as $\tau = 1.9$ to present corresponding distributions of stresses and displacement. Between Figures 6.39 and 6.42, 0.2 time increments are used to plot distributions of the response variables. In the last figure, which is plotted at time instant $\tau = 2.7$, the temperature cycle ends and the surface temperature returns to reference temperature. In this cooling time interval, it is visible from the figures that stresses and especially displacement decrease dramatically with time after unloading starts. Additionally, it should be remained that plastic strains for these time instants are the same as those given in Figure 6.34. For these figures, the non-dimensional unknown constants \bar{C}_2^* and $\bar{\epsilon}_0$ are calculated with help of Eqs. (5.24–5.25) and the results are presented in Table 6.4.

Table 6.4: Calculated constants in unloaded state at different time values until the end of the temperature cycle

Time (τ)	\bar{C}_2^*	$\bar{\epsilon}_0$
1.7882(τ_{ub})	0.304070	0.355186
1.9	0.300530	0.305625
2.1	0.293728	0.210395
2.3	0.286692	0.111895
2.5	0.279583	1.236726×10^{-2}
2.7	0.272450	-8.748429×10^{-2}

It certainly takes time to reach homogeneous temperature distribution in the whole shaft after reaching reference temperature of the outer surface as followed in Figure 6.6. Hence, until isothermal case is obtained, stresses and displacement in the shaft can vary with time at any point. These distributions are plotted for following time values: $\tau = 3.0$ in Figure 6.43, $\tau = 3.6$ in Figure 6.44, $\tau = 4.0$ in Figure 6.45, $\tau = 10.0$ in Figure 6.46, and $\tau = 20.0$ in Figure 6.47. As seen, there are not any differences

between Figure 6.46 and Figure 6.47. This shows that when time reaches to $\tau = 20.0$, the shaft behaves isothermal. Then thermal load is removed totally from the shaft. Integration constants that are obtained to plot Figures from 6.43 to 6.47 are presented in Table 6.5.

Table 6.5: Calculated constants in unloaded state at different time values after the temperature cycle

Time (τ)	\bar{C}_2^*	$\bar{\epsilon}_0$
3.0	0.268744	-0.139379
3.6	0.268014	-0.149588
4.0	0.267993	-0.149884
10.0	0.267991	-0.149916
20.0	0.267991	-0.149916

An interesting result is observed on the evolution of stresses and radial displacement with time at some critical locations, i.e., the center ($x = 0$) and the outer surface ($x = 1$) of the shaft. In Figure 6.48, the evolution of the radial stress at the center with time is presented. In the figure, the critical time values, i.e., the end of the heating time τ_t , the beginning of the cooling time $\tau_t + \tau_c$, the end of the cooling time $2\tau_t + \tau_c$, the time when plastic flow starts τ_p and the time when unloaded state starts τ_{ub} , separate the time intervals. As seen in the figure, the stress tends to vary at each time interval in different manner. The radial stress at the center initially increases during the surface heating process ($\tau \leq \tau_t$). On the other hand, it dramatically decreases with different slopes at the time interval when the surface temperature remains constant and in the cooling time interval ($\tau_t \leq \tau \leq 2\tau_t + \tau_c$). When the outer surface temperature reaches back to the reference temperature at $\tau = 2\tau_t + \tau_c$, the radial stress starts to increase again. However, the stress tends to a certain value, which is $\bar{\sigma}_r = 1.1043$, with increasing time since the rotation speed is constant and the isothermal case is approaching. This value is higher than the initial one (at $\tau = 0$) and this proves that some residual stresses remain in the shaft because of the temperature field. It should also be noted that this evolution is the same as the evolution of circumferential stress at the center since $\sigma_r = \sigma_\theta$ at this location.

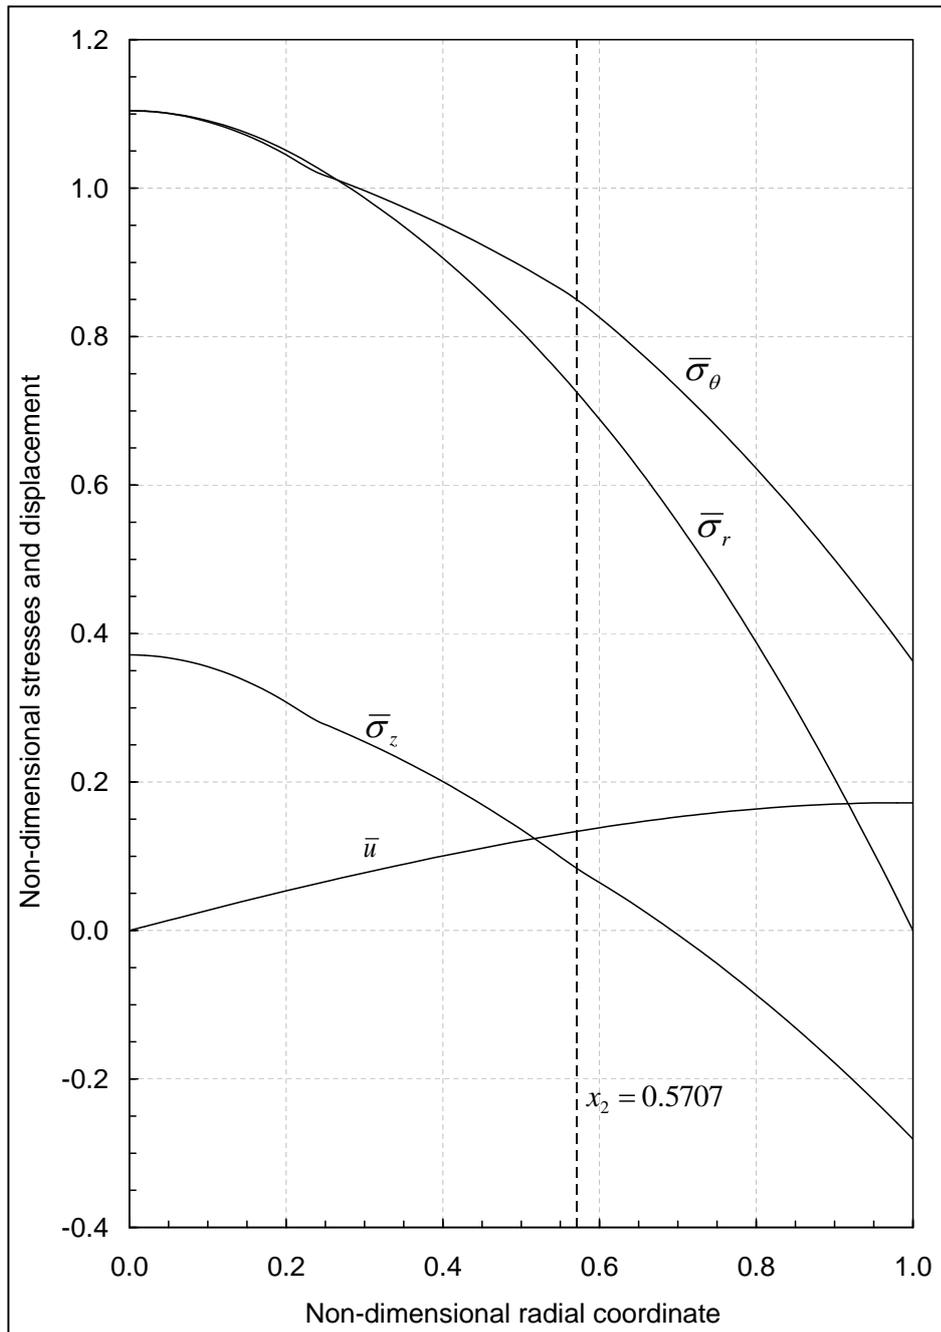

Figure 6.47: Stresses and radial displacement distributions in unloaded state at $\tau = 20.0$

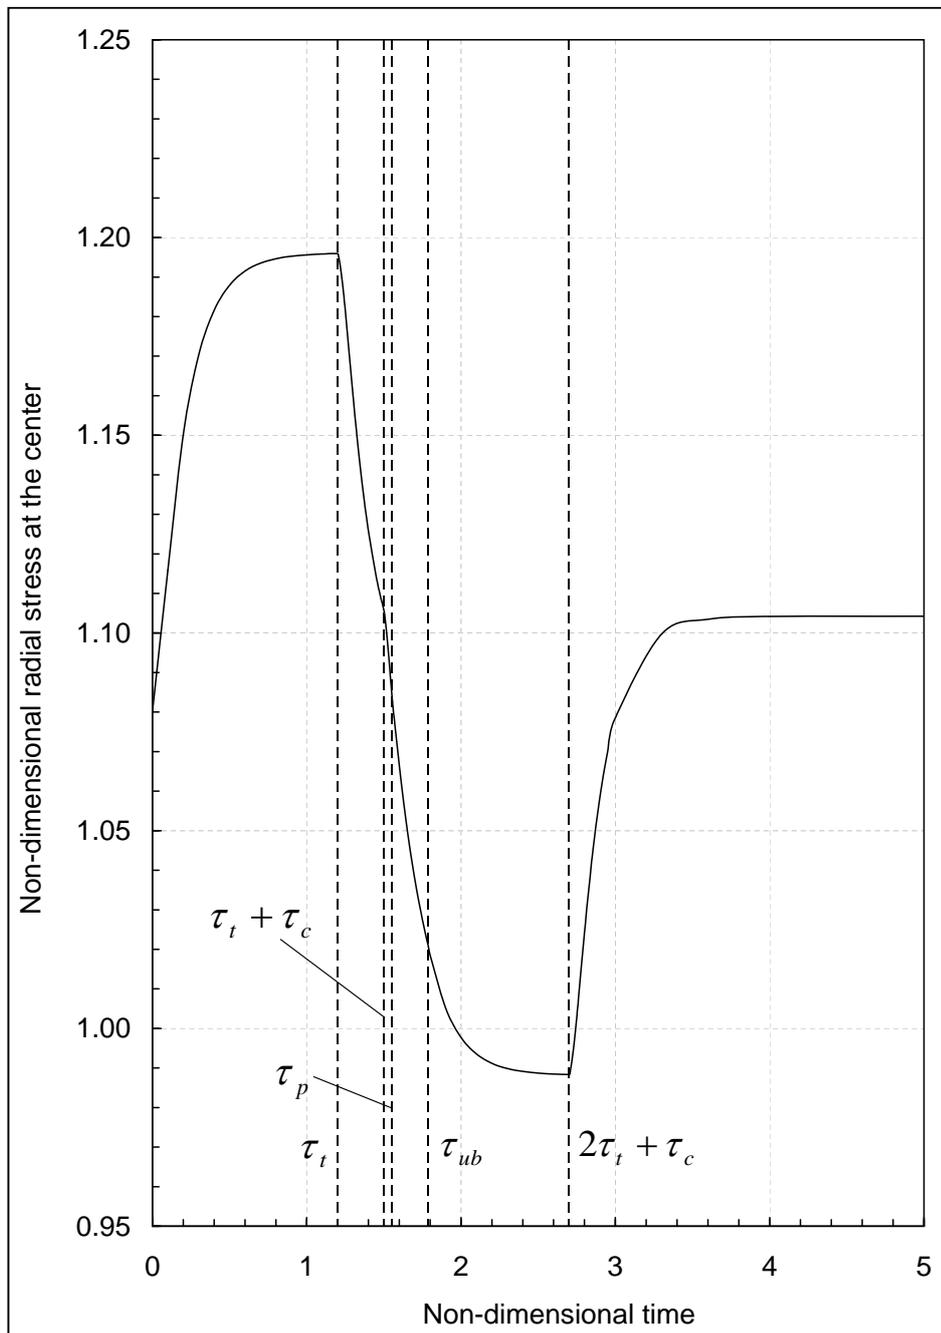

Figure 6.48: Evolution of the radial stress at the center of the shaft

In Figure 6.49, the evolution of the circumferential stress at the surface of the shaft is presented. The behavior of the circumferential stress at $x = 1$ is the opposite of that at $x = 0$. In Figures 6.50 and 6.51, the evolution of axial stresses at the center and the outer surface are plotted, respectively. These two figures show that adverse behavior is observed at the center and the outer surface for the axial stress. Lastly, the evolution of the radial displacement component at the outer surface of the shaft is presented in Figure 6.52. The displacement increases with the superposition of the rotation and the surface heating until $\tau = \tau_t + \tau_c$. However, it decreases during the cooling of the outer surface and becomes constant at $\bar{u} = 0.1719$.

As seen in Figures from 6.48 to 6.52, some differences occur between the beginning and the end of the thermal process for stresses ($\bar{\sigma}_i|_{\tau=5} - \bar{\sigma}_i|_{\tau=0}$) and radial displacement ($\bar{u}|_{\tau=5} - \bar{u}|_{\tau=0}$) because of the residual effects. These differences are calculated and presented in Table 6.6. As seen in the table, the maximum difference is observed in the axial stress at the center of the shaft. However, differences in the other stresses and radial displacement are very small.

Table 6.6: Differences in response variables between the beginning and the end of the thermal process

$\bar{\sigma}_r(0) _{\tau=5} - \bar{\sigma}_r(0) _{\tau=0}$	=	0.024259,
$\bar{\sigma}_\theta(1) _{\tau=5} - \bar{\sigma}_\theta(1) _{\tau=0}$	=	0.002590,
$\bar{\sigma}_z(0) _{\tau=5} - \bar{\sigma}_z(0) _{\tau=0}$	=	0.101247,
$\bar{\sigma}_z(1) _{\tau=5} - \bar{\sigma}_z(1) _{\tau=0}$	=	-0.011005,
$\bar{u}(1) _{\tau=5} - \bar{u}(1) _{\tau=0}$	=	0.002266.

During the unloaded state, the ratio of the equivalent and the yielding stresses should be less than 1. To observe this, the distribution of $\bar{\sigma}_y/\bar{\sigma}_{th}$ on radial direction for different times is presented in Figure 6.53. This ratio decreases with time since the thermal effect slowly disappears and thus the isothermal case is obtained. Finally, when the time approaches to nearly or higher value than $\tau = 5.0$, the ratio of $\bar{\sigma}_y/\bar{\sigma}_{th}$ remains constant in the whole shaft. Furthermore, Figure 6.54 shows the evolution of ratio of equivalent and yield stresses with increasing time at the center of the shaft. It should be noted that at $\tau \approx 1.9$ the ratio of $\bar{\sigma}_y/\bar{\sigma}_{th}$ is higher than 1. The reason for this overlap is the approximated unloading and is described in Figure 6.36.

For completeness, the stresses after stand-still are shown on Figure 6.55. The distributions of stresses are plotted at $\tau = 20.0$ and for $\Omega = 0$. In other words, the thermal effect is far away and the rotation is stopped. Hence, these stresses are called residual stresses that remain in the shaft because of the thermal and the mechanical loading. As can be seen from the figure, secondary plastic flow does not occur.

In Figure 6.56, Tresca's yield conditions are presented in the usual way as Tresca's hexagon in the deviatoric plane of the three-dimensional stress space. These figures show four phases of the development of the plastic flow occurring in a rotating solid shaft under unsteady thermal load. Figure 6.56.a is sketched at $\tau = \tau_p$. As seen, yielding occurs when the stress image point at $x = 0$ reaches an edge regime of the Tresca's hexagon in principal stress space. Additionally, $x = x_1$ and $x = x_2$ are also seen at the same point at the onset of the yielding. At this time, outer part of the shaft is still elastic then remaining part of the stress space is on the inside of the hexagon. With increasing time, for which $\tau_p < \tau < \tau_{ub}$, x_2 moves on the one side of Tresca's hexagon according to yield condition (see also Figure 2.2) as seen in Figure 6.56.b. Stress field onto deviatoric plane of the principal stress space at $\tau = \tau_{ub}$ and for $\tau > \tau_{ub}$ are given in Figures 6.56.c and 6.56.d, respectively. As seen in Figure 6.56.d, the stress space is on the inside of the hexagon since the secondary yielding does not occur during unloading.

In Figure 6.57, the evolution of the elastic and the plastic regions are summarized by sketching them at the cross-section of the shaft. The evolution of the regions at different times are plotted respectively. The evolution starts with the purely elastic state at $\tau = \tau_p = 1.5519$ and for $\Omega = 0.9 \times \Omega_e^i = 1.5875$ as seen in Figure 6.57.a. Only elastic region appears in the figure. Additionally, at this time, plastic flow starts, too and moves to the outer zone of the shaft with the increasing time as seen in the Figures from 6.57.b to 6.57.l. In these figures, all regions are drawn with different shapes to make a distinction among the evolution of them. At $\tau = \tau_{ub} = 1.7882$, the unloading starts and then the predeformed elastic region remains on the inner zone of the shaft as seen in Figures from 6.57.m to Figure 6.57.o. In the last one, all loads have been removed, i.e., rotation is stopped in the isothermal shaft.

6.3 Summary and Discussion

The closed form solution to a rotating solid shaft with the temperature dependent yield stress under a temperature cycle is presented. The shaft is subjected to a centrifugal force due to the rotation and an unsteady-state thermal load due to temperature cycle, i.e., the temperature of its surface is increased slowly and linearly with time, held constant for some time, and then decreased linearly with time to its reference temperature. Thermally induced wave phenomena is vanished since the thermal load is applied slowly. Elastic-plastic state of stress is presumed to obey Tresca's yield criterion and the associated flow rule with it. Furthermore, state of generalized plane strain and circular symmetry are considered.

The earlier studies, which are related to the present thesis, are separated into three categories. In the first category, the investigations which include elastic or elastic-plastic solutions of the cylindrical machine elements that are subjected to solely rotation are presented. The second category consists of the analysis for the non-rotating cylindrical elements under only thermal load. Investigation of the deformation due to superposition of these two loads on a disk or shaft are presented under title of the third category. The literature review shows the requirement of the theoretical investigation for the problem of an elastic-plastic rotating solid shaft, which is one of the most wide-spread machine parts, under unsteady thermal load, in which interesting and unpredictable results may be expected.

Initially, the entire shaft is presumed to be in a purely elastic state. As soon as the yielding condition is satisfied, two different plastic regions emerge at the center of the shaft, simultaneously. They expand into the elastic region in time until an elastic unloading occurs at the plastic-elastic interface radius. Next, plastic regions do not move into elastic region anymore. On the other hand, the predeformed elastic region spreads rapidly into the plastic zone. For the mathematical model of this elastic-plastic behavior, the governing equations and their analytical solutions for these regions are obtained with the help of the basic equations. These solutions may include unknown integration constants, axial strain and the interface radii. To evaluate each unknown value in the purely elastic state, elastic-plastic state and approximated unloaded state, boundary and interface conditions are used. The analytical expressions

for the calculation of integration constants are also derived. The rest of the unknowns are calculated numerically. Finally, numerical results of the problem for the chosen parameters are presented.

CHAPTER 7

CONCLUSION

First, for certain combinations of the parameter values a qualitatively different behavior, such as partial or full plasticization, may occur by depending on the loading conditions. Nevertheless, the results which are presented in Section 6.2 may be considered characteristic for a wide class of the shafts under similar conditions.

Secondly, starting at the center, the plasticization may occur even in the shafts which have been designed purely elastic. Remarkably, at least if pronounced temperature gradients occur, this happens only after the temperature of the surface has started to decrease again. The delay in the beginning of the plasticization and hence also in the beginning of the unloading may be attributed to the inhomogeneity of the temperature field.

Additionally, from the engineering point of view, the stress distribution after complete cooling and stand-still is of particular interest. It can be concluded that, all of these residual stresses are small as compared to yield limit. Remarkably, the residual stresses, after stand-still, with any smaller angular speed remain far beyond the secondary yield limit. As a further interesting result, the axial stress in the centre is found to be dominating one.

Finally, it should be pointed out that prior to unloading the numerical effort essentially is restricted to the solution of an algebraic system of equations; if the proposed approximate calculation of the stresses after unloading is applied, in the later stages only numerical integrations must be added. As the error introduced by the approximation is very small, significant benefits by applying much more complex purely numerical methods like FE-codes are hardly to be expected.

APPENDIX A

DESCRIPTION OF FORTRAN CODES

Integration constants, axial strain, interface radii, analytical and numerical integrals, and Bessel and hypergeometric functions are calculated by using Fortran 77 codes. In the codes, non-dimensional and normalized variables and equations are used. The codes are divided into three categories since three states of stress, which are purely elastic state, elastic-plastic state and unloaded state, are examined in the study.

The first category includes Fortran codes for the purely elastic state (see Appendix B). All codes in Appendix B (Appendices B1–B6) are compiled and run in the same project since the main program is connected to the other subroutines and functions by common block or dummy arguments. The main program in the first category is called *Purely Elastic State* (see Appendix B.1). In this program, after the introduction of the input parameters, unknown non-zero constants are calculated (with the help of Eqs. (5.2) and (5.3) in dimensional form) and substituted into analytical expressions of response variables (Eqs. (4.22)–(4.25)) at different radial coordinates. By manipulating the non-dimensional time value, different distribution of the response variables are obtained. During all these calculations, temperature distribution and a temperature integral are calculated for each time and radial coordinate by using the subroutine called *Temperature Distribution* (See Appendix B.2). In the subroutine, the temperature and some integrals are superposed according to time interval by using Eqs. (3.11). This subroutine takes the temperature and its integral by the connections to the Fortran functions called *Temperature* (Appendix B.3) and *Temperature Integral 1* (Appendix B.4). The first function calculates the non-dimensional temperature distribution given Eq. (3.9) and the second one calculates an exact temperature integral, which is given in Eq. (4.20). Furthermore, the summation of the series in these tem-

perature equations are computed by using Fortran functions *Series 1* (Appendix B.5) and *Series 2* (Appendix B.6). The Bessel functions and roots that appear in these series may be computed by any Fortran subroutine. This subroutine calculates roots of the zeroth order Bessel functions of the first kind γ_n according to Eq. (3.10) and, the zeroth and the first order Bessel functions of the first kind J_0 and J_1 . However, this subroutine is not presented here. Finally, by executing the main program and the connected five Fortran subroutines and functions, the response variables on the purely elastic state are calculated and written into an output data file. For continuity of the process, the instant time value is increased slowly by hand. However, the usage of these subroutines are valid until a time value when the yielding conditions are satisfied (Eq. (4.29)). After this certain time value, this codes become out of use since plastic flow starts. For the following time values, the codes, which are written for the second category, should be executed.

In the second category, Fortran codes for the numerical results of the elastic-plastic state are considered. To calculate the results in this state, beside the codes presented in Appendix C, those in Appendices B2–B6 are performed simultaneously. The main program in this category is called *Elastic Plastic state* (Appendix C.1). This program is designed to initially calculate six integration constants ($C_1 - C_6$) analytically; then, to compute three unknowns (ϵ_0, r_1 and r_2) numerically (since a non-linear equation system is obtained for the border radii) and lastly, to figure out the response variables in the elastic-plastic state. Analytical expressions for six integration constants are placed into subroutine *NLNEQN* (Appendix C.2). Moreover, this subroutine includes interface and boundary conditions (Eqs. (5.9), (5.10) and (5.14)) to compute the remaining unknowns. To compute these unknowns, subroutine *HYBRD1*, which is implemented in the program called *MINPACK* is performed. The Fortran program *MINPACK* is a non-linear equation system solver which uses the Powell Hybrid Method (see [75]). The connection between the main program and Minpack is provided by *NLNEQN*. After the calculation of the all unknowns, the response variables are obtained by making use of the subroutines *Plastic Region I*, *Plastic Region II* and *Elastic Region* (Appendices C.3–C.5). These subroutines include analytical expressions for three regions. The main program executes these subroutines for different radial coordinates and writes the results in an output data file. Similar to first codes

category, the temperature distribution, the first temperature integral and summation of the first two series are calculated by using the codes given in Appendices B2–B6 in this codes category, too. Additionally, Fortran function *Temperature Integral 2* (Appendix C.6) is performed to calculate temperature integrals in Eqs. (4.76) and (4.82). The summation of the series in these equations are calculated with the help of function *Series 3* (Appendix C.7). Unlike others, these integral equations include hypergeometric functions and these functions are calculated by using the Fortran codes called *Hypergeometric Function* (Appendix C.8). The Fortran codes in the second category may be used until the time when unloading conditions (Eq. (5.21)) are observed in the results. For the following time values, the codes of third category, which are prepared for the unloaded state, should be run.

The third category of the codes is used to calculate response variables in unloaded state. The Fortran codes used in this category in addition to codes in Appendix B.2–B.6 are presented in Appendix D. The main program called *Unloaded State* (see Appendix D.1) is executed with codes above mentioned, namely, *Temperature Distribution*, *Temperature*, *Temperature Integral 1*, *Series 1* and *Series 2*. The main program is arranged to calculate two non-zero unknown constants (C_2^* and ϵ_0) with the help of Eqs. (5.24) and (5.25) and to substitute these constants into analytical expressions of response variables. In this process, it is necessary to access the values of permanent plastic strains (ϵ_i^{pr}) seen in the equations in the Chapter 4.5. The permanent plastic strains are the ones which are computed in the program of Elastic-plastic state (with the second category of the codes) at a time when the unloading starts. Hence, the codes in the second category are run one more time and the calculated plastic strains are written into a data file. The tabulated form of this data file, which is called *Permanent Plastic Strains*, for the prescribed input parameters is given in Table D.1 in Appendix D.2. The main program calls this file as an input. In the calculations of the unloaded state, we need to calculate some integral which include the permanent plastic strains as given below.

$$\text{INTEPS1} = \int_0^r \frac{\epsilon_r^{pr} - \epsilon_\theta^{pr}}{\xi} d\xi, \quad (\text{A.1})$$

$$\text{INTEPS2} = \int_0^r \xi (\epsilon_r^{pr} + \epsilon_\theta^{pr}) d\xi. \quad (\text{A.2})$$

The numerical integrations of these discrete permanent strain values are performed by

the Fortran program DAVINT efficiently. DAVINT, which is documented completely in SC-M-69-335, integrates a function tabulated at arbitrarily space abscissas. This Fortran program is the adapted and modified (by Rondall E. Jones) form of AVINT, which is prepared by Davis and Rabinowitz [76]. Finally, all of these codes with the input data file are executed for different time values and the response variables are written into output data file for the unloaded state.

APPENDIX B

FORTRAN CODES OF PURELY ELASTIC STATE

B.1 MAIN PROGRAM: PURELY ELASTIC STATE

```
PROGRAM PURELY ELASTIC STATE
C -----
C   PURPOSE:
C -----
C   This program calculates the non-dimensional response variables in
C   the purely elastic state for the problem of rotating solid shaft
C   subjected to temperature cycle. All calculations are done for
C   non-dimensional parameters. Input parameters, which are described
C   below, are initially introduced. Then non-zero integration
C   constant C2 and axial strain EPS0 are calculated by using the
C   analytical expressions. Substituting the parameters and constants
C   into the response variable leads to obtain output values at N1
C   radial points in the shaft. Results are printed to the output file,
C   which is titled 'A-ELAST.DAT'.
C   The program is connected to subroutine 'DISTRIBUTION' to call
C   TBAR and INT1. Subroutine 'DISTRIBUTION' is used to calculate some
C   integrals which include temperature terms. By substituting variable
C   R and the upper limits of the integral, INT1 is calculated
C   analytically by using this subroutine. Additionally, this
C   subroutine is also used to get TBAR which is non-dimensional
C   temperature distribution.
C -----
C   CONNECTED SUBROUTINES
C -----
C   1) DISTRIBUTION (R, TBAR, ULIM, INT1, POW, INT2E).
C -----
C   DESCRIPTION OF PARAMETERS:
C -----
C   INPUT:
C   BETA      : Non-dimensional temperature dependence parameter of
C               the material.
C   NU       : Poisson's ratio.
C   N1       : Number of data points in the shaft.
C   OMEGA    : Non-dimensional angular velocity.
C   Q        : A non-dimensional measure for the maximum surface
```

```

C          temperature during the transient heating.
C      R      : Non-dimensional radial coordinate.
C      TAU     : Non-dimensional instant time.
C      TAUT    : The non-dimensional time value when surface heating
C              ends.
C      TAUC    : The non-dimensional time value that the surface
C              temperature is held constant at maximum temperature
C              value.
C
C      OUTPUT:
C      C2      : Non-zero, non-dimensional integration constant
C      EPS0    : Non-dimensional axial strain.
C      SIGR    : Non-dimensional radial stress component.
C      SIGT    : Non-dimensional circumferential stress component.
C      SIGZ    : Non-dimensional axial stress component.
C      SIGTHER : Non-dimensional yield stress.
C      SIGY    : Non-dimensional equivalent stress.
C      U       : Non-dimensional radial displacement component.
C
C      IMPLICIT NONE
C      INTEGER I, N1
C      DOUBLE PRECISION TBAR, R, TAU, TAUT, TAUC, ULIM, TBARINT, TERM1,
1          NU, Q, OMEGA, C2, DR, TERM2,

APPENDIX C

FORTRAN CODES OF ELASTIC-PLASTIC STATE

C.1 MAIN PROGRAM: ELASTIC-PLASTIC STATE

```
PROGRAM ELASTIC PLASTIC STATE
C -----
C   PURPOSE:
C -----
C   This program is used to calculate the non-dimensional response
C   variables in the elastic-plastic state for the problem of rotating
C   solid shaft subjected to temperature cycle. All calculations are
C   done for non-dimensional parameters. In this state, six integration
C   constants, 2 interface radius and the axial strain is need to be
C   computed. The integration constants are already calculated
C   analytically in subroutine NLNEQN, which is externally called by
C   the present program, and they are moved to the current program by
C   COMMON command. However, resulting system of equations are
C   non-linear in the border radii. Hence, remaining three unknowns
C   are needed to be computed numerically. This is done by the Powell
C   Hybrid Method implemented in the program Minpack.for. Therefore,
C   HYBRD1 is called to solve three unknowns numerically. For the
C   present algorithm, input and output parameters are given below.
C   Furthermore, Subroutine 'DISTRIBUTION' is used to calculate some
C   integrals which include temperature terms. By substituting variable
C   R, power M and the upper limits of the integral, INT1 and INT2E are
C   calculated analytically by this subroutine. Additionally, this
C   subroutine is also used to get TBAR which is non-dimensional
C   temperature distribution.
C   The problem is formulated for solid shaft. Hence, there is not an
C   inner radius. However, for numerical calculation, an inner surface
C   radius is needed to be defined. Therefore, a sufficiently small
C   inner radius A is defined as 0.1D-10.
C   After the definition of input parameters (NU,Q,BETA,OMEGA,TAU,
C   TAUT,TAUC), initial estimates are done for EPS0, R1 and R2. These
C   estimations are sent to HYBRD1 with system of equations defined in
C   NLNEQN. If program converges perfectly with the tolerance defined,
C   input and output parameters are written into A-FIRST-STAGE.DAT.
C   Response variables are calculated for each regions at N1,N2 and
C   N3 points and results are printed to the same output file.

C -----
C DESCRIPTION OF PARAMETERS:
C -----

C INPUT:

- C A : Sufficiently small inner radius for solid shaft
C (it is assumed as 1.0D-10).
C BETA : Non-dimensional temperature dependence parameter of
C the material.
C C1-C6 : Non-dimensional integration constants (calculated
C analytically in subroutine NLNEQN and inserted to
C the current program). (from COMMON block)
C M : A power that is introduced in plastic region II.
C ND : A positive integer input variable set to the number
C of functions and variables in non-linear equation
C system solver.
C NU : Poisson's ratio.
C N1,N2,N3: Number of data points in plastic region I, plastic
C region II and elastic region, respectively.
C OMEGA : Non-dimensional angular velocity.
C Q : A non-dimensional measure for the maximum surface
C temperature during the transient heating.
C R : Non-dimensional radial coordinate.
C TAU : Non-dimensional instant time.
C TAUT : The non-dimensional time value when surface heating
C ends.
C TAUC : The non-dimensional time value that the surface
C temperature is held constant at maximum temperature
C value.
C TOL : Tolerance on the solution of the nonlinear equation
C system. It is a nonnegative input variable.
C Termination occurs when the algorithm estimates that
C the relative error between X and this solution is at
C most TOL.

C OUTPUT:

- C EPSR : Non-dimensional radial plastic strain.
C EPST : Non-dimensional circumferential plastic strain.
C EPSZ : Non-dimensional axial plastic strain.
C EPSO : Non-dimensional axial strain (initially estimated,
C then exact value is computed).
C INFO : An integer output variable which gives information
C concerning terminated execution in non-linear system
C solver.
C R1 : Non-dimensional interface radius between plastic
C region I and II (initially estimated, then exact

```

C          value is computed).
C      R2      : Non-dimensional interface radius between plastic
C              region II and elastic region (initially estimated,
C              then exact value is computed).
C      SIGR     : Non-dimensional radial stress component.
C      SIGT     : Non-dimensional circumferential stress component.
C      SIGZ     : Non-dimensional axial stress component.
C      SIGTHER  : Non-dimensional yield stress.
C      SIGY     : Non-dimensional equivalent stress.

C.2 SUBROUTINE: NLNEQN

```
SUBROUTINE NLNEQN (NDIM, X, F, IFLAG)
C -----
C   PURPOSE:
C -----
C   This subroutine is used to introduce functions F which describe
C   interface and boundary conditions. The array F is obtained and
C   sent to iterations in HYBRD1.
C   In each loop, estimated EPS0, R1 and R2 are taken from HYBRD1
C   and substituted into analytical expressions being for six
C   integration constants. Then new F are computed by using interface
C   and boundary conditions and sent back to HYBRD1. These loops are
C   proceeding until the tolerance condition is satisfied in HYBRD1.
C   All expressions are in non-dimensional form.
C -----
C   CONNECTED SUBROUTINES
C -----
C   1) DISTRIBUTION (R, TBAR, ULIM, INT1, POW, INT2E).
C -----
C   DESCRIPTION OF PARAMETERS:
C -----
C   INPUT:
C   EPS0      : Non-dimensional axial strain (exact value for EPS0
C               is taken from subroutine NLNEQN).
C   F         : Functions, which include interface and boundary
C               conditions, is used to estimate X.
C   R1        : Non-dimensional interface radius between plastic
C               region I and II (exact value for EPS0
C               is taken from subroutine NLNEQN).
C   R2        : Non-dimensional interface radius between plastic
C               region II and elastic region (exact value for EPS0
C               is taken from subroutine NLNEQN).
C   X         : An array which the final estimate of the solution
C               vector in HYBRD1) (dummy arguments)
C   OUTPUT:
C   C1-C6     : Non-dimensional integration constants (calculated
C               analytically).

C.7 FUNCTION: SERIES 3

```

DOUBLE PRECISION FUNCTION SER_3 (M, TAU, X)
C      -----
C      PURPOSE:
C      -----
C      SER_3 is the summation of the series which is used in INT_2E.
C      These series include Bessel roots (R) and one Bessel function
C      (first order Bessel functions of the first kind). Initially, first
C      1250 roots of zeroth order Bessel functions of the first kind (R)
C      is found (it is possible to use any subroutine to find root of
C      Bessel functions but it is not given here). Then first order Bessel
C      functions of the first kind DBESJ1(R) are computed for each R (The
C      algorithm of this Bessel function is not either given here).
C      Furthermore, HYPPFQ(A1, A2, A3, Z) being a hypergeometric function
C      is called. Finally, SER_3 is calculated by substituting Bessel
C      functions for each root R and hypergeometric function into T. All
C      calculations are done for non-dimensional parameters.

FORTRAN CODES OF UNLOADED STATE

D.1 MAIN PROGRAM: UNLOADED STATE

```
PROGRAM UNLOADED STATE
C -----
C   PURPOSE:
C -----
C   This program is used to calculate the non-dimensional response
C   variables in the unloaded state for the problem of rotating solid
C   shaft subjected to temperature cycle. The input parameters radial
C   coordinate and permanent plastic strains are read from an input
C   file 'A-PERSTRAIN.DAT'. This file includes radial coordinate and
C   permanent plastic strains at NTOT data points. Permanent plastic
C   strains at NTOT data point are the plastic strains which are
C   computed in the program ELASTIC PLASTIC STATE at time when the
C   unloading state starts. After reading these parameters from the
C   input file unknown constants C1, C2 and EPS0 are calculated
C   analytically. During this calculation, subroutines 'DAVINT' and
C   'DISTRIBUTION' are called.
C   Subroutine 'DAVINT' is used to compute some integral numerically
C   which include permanent plastic strains. During calling DAVINT,
C   argument X, integral function F, lower and upper limits of the
C   integrals are prescribed. Numerical result of the integral is ANS.
C   Subroutine 'DISTRIBUTION' is used to calculate some integrals
C   which include temperature terms. By substituting variable X and
C   the upper limits of the integral, INT1 is calculated analytically
C   by this subroutine. Additionally, this subroutine is also used
C   to get TBAR which is non-dimensional temperature distribution.
C   Then response variables are calculated by using subroutines
C   above and analytical expressions at NTOT radial coordinates.
C   Results are written into the file 'A-OUTPUT.DAT'.
C   All calculations are done for non-dimensional parameters.
C -----
C   CONNECTED SUBROUTINES AND DATA FILES
C -----
C   1) A-PERSTRAIN.DAT,
C   2) DAVINT (X, Y, N, XLO, XUP, ANS, IERR) (Implemented in
C       Davint.for),
C   3) DISTRIBUTION (R, TBAR, ULIM, INT1, POW, INT2E).

```

C      DESCRIPTION OF PARAMETERS:
C      -----
C      INPUT:
C      BETA      : Non-dimensional temperature dependence parameter of
C                  the material.
C      EPSRP     : An array which includes permanent plastic radial
C                  strain at NTOT data points. These strains are
C                  generated by using program 'ELASTIC PLASTIC STATE'
C                  at the time value when unloading starts and written
C                  into 'A-PERSTRAIN.DAT'. (from data file)
C      EPSTP     : An array which includes permanent plastic circumferential
C                  strain at NTOT data points. These strains are
C                  generated by using program 'ELASTIC PLASTIC STATE'
C                  at the time value when unloading starts and written
C                  into 'A-PERSTRAIN.DAT'. (from data file)
C      EPSZP     : An array which includes permanent plastic axial
C                  strain at NTOT data points. These strains are
C                  generated by using program 'ELASTIC PLASTIC STATE'
C                  at the time value when unloading starts and written
C                  into 'A-PERSTRAIN.DAT'. (from data file)
C      NTOT      : Number of data points. (according to data file)
C      NU        : Poisson's ratio.
C      OMEGA     : Non-dimensional angular velocity.
C      Q         : A non-dimensional measure for the maximum surface
C                  temperature during the transient heating.
C      R         : Non-dimensional radial coordinate.
C      TAU       : Non-dimensional instant time.
C      TAUT      : The non-dimensional time value when surface heating
C                  ends.
C      TAUC      : The non-dimensional time value that the surface
C                  temperature is held constant at maximum temperature
C                  value.
C      X         : An array which include NTOT non-dimensional radial
C                  coordinate values (R) and read from 'A-PERSTRAIN.DAT'.
C                  X(1)=0 and X(NTOT)=1. (from data file)
C      OUTPUT:
C      C2        : Non-zero, non-dimensional integration constant
C      EPS0      : Non-dimensional axial strain.
C      EPSRPU    : Non-dimensional permanent plastic radial strain which
C                  remains in the shaft during plastic flow.
C      EPSTPU    : Non-dimensional permanent plastic circumferential strain
C                  which remains in the shaft during plastic flow.
C      EPSZPU    : Non-dimensional permanent plastic axial strain which
C                  remains in the shaft during plastic flow.
C      SIGR      : Non-dimensional radial stress component.
C      SIGT      : Non-dimensional circumferential stress component.
C      SIGZ      : Non-dimensional axial stress component.
C      SIGTHER   : Non-dimensional yield stress.
C      SIGY      : Non-dimensional equivalent stress.
C      U         : Non-dimensional radial displacement component.

C      -----
C      A loop is generated to compute the response variables.
C      For the radial coordinates from R=0 to R=1, INTEPS1 and INTEPS2
C      are obtained by calling subroutine 'DAVINT', TBARINT is computed
C      by using subroutine 'DISTRIBUTION' in NTOT data points. Limiting
C      case for these integrals are described when R approaches to 0.
C      Lastly, the response variables are calculated at NTOT data points
C      and written into the output file.

CURRICULUM VITAE

PERSONEL INFORMATION

Surname, Name : Arslan, Eray
Nationality : Turkish (TC)
Date and Place of Birth : 1 July 1981, Adana
Marital Status : Single
Email : erarslan@metu.edu.tr

EDUCATION

Degree	Institution	Year of Graduation
BS	Çukurova University Mechanical Eng.	2003
High School	Halide Edip Lisesi, Ankara	1998

WORK EXPERIENCE

Year	Place	Enrollment
2004-Present	METU Department of Engineering Sciences	Research Assistant

FOREIGN LANGUAGES

Advanced English, Basic German

PUBLICATIONS

- 1) Arslan E., Mack W., Eraslan, A.N.: The rotating elastic-plastic hollow shaft conveying a hot medium. *Forschung im Ingenieurwesen / Engineering Research*. (to appear).
- 2) Arslan E., Eraslan, A.N.: Analytical solution to the bending of a nonlinearly hardening wide curved bar. *Acta Mechanica* 210, 71-84 (2010).
- 3) Eraslan, A.N., Arslan E.: A Computational Study on the Nonlinear Hardening Curved Beam Problem. *International Journal of Pure and Applied Mathematics* 43, 129-143 (2008).
- 4) Eraslan, A.N., Arslan E.: A Concise Analytical Treatment of Elastic-plastic Bending of a Strain Hardening Curved Beam. *Zeitschrift für Angewandte Mathematik und Mechanik (ZAMM)* 88 No. 8, 600-616 (2008).
- 5) Arslan E., Mack W., Eraslan, A.N.: Effect of a temperature cycle on a rotating elastic-plastic shaft. *Acta Mechanica* 195, 129-140 (2008).

6) Eraslan, A.N., Arslan E.: Plane Strain Analytical Solutions to Rotating Partially Plastic Graded Hollow Shafts. Turkish Journal of Engineering and Environmental Sciences 31, 273-288 (2007).

7) Eraslan, A.N., Arslan E., Mack W.: The strain hardening rotating hollow shaft subject to positive temperature gradient. Acta Mechanica 194, 191-211 (2007).

INTERNATIONAL CONFERENCE PROCEEDINGS

1) Arslan, E., Mack, W., Eraslan, A. N., "The rotating elastic-plastic hollow shaft heated at its inner surface", 80th Annual Meeting of the International Association of Applied Mathematics and Mechanics (GAMM), Gdansk, Poland, 4-9 February 2009.

2) Arslan, E., Mack, W., Eraslan, A. N., "Transient heating of a rotating elastic-plastic solid shaft", 79th Annual Meeting of the International Association of Applied Mathematics and Mechanics (GAMM), Bremen, Germany, 31 March- 4 April 2008, (PAMM · Proc. Appl. Math. Mech. 8, 10257 – 10258 (2008) / DOI 10.1002 / pamm.200810257).

3) Arslan, E., Eraslan, A. N., Mack, W. "Elastic-plastic states of a rotating inhomogeneously heated strain hardening hollow shaft", 6th International Congress on Industrial and Applied Mathematics GA/CT1952/004, Zurich, Switzerland, 16-20 July 2007, (PAMM Proc. Appl. Math. Mech. 7, 4040051 – 4040052 (2007) / DOI 10.1002 / pamm.200701082)

4) Eraslan, A. N., Arslan, E., "Numerical Solution of Partially Plastic Curved Beam Problem", III European Conference on Computational Mechanics Solids, Structures and Coupled Problems in Engineering, Lisbon, Portugal, 5-8 June 2006, proceeding no: 1232.

NATIONAL CONFERENCE PROCEEDINGS

1) Arslan E., Eraslan, A. N. "Doğrusal Olmayan Pekleşme Davranışı Gösteren Eğri Eksenli Kirişin Basit Eğilme Altında Analitik Çözümü: Kısmen Plastik ve Artık Gerilme Halleri", 16. Ulusal Mekanik Kongresi, Kayseri, Nisan 2009.

2) Arslan E., Eraslan, A. N. "Kısmen Plastik Eğri Eksenli Kiriş Probleminin Basit Eğilme için Analitik Çözümü", 15. Ulusal Mekanik Kongresi, Isparta, Eylül 2007, pp. 117-124.

3) Eraslan, A. N., Arslan E. "Fonksiyonel Derecelendirilmiş Dönen Milin Elastoplastik Analitik Çözümü", 14. Ulusal Mekanik Kongresi, Antakya, Eylül 2005, pp. 389-395.
