

POST-LATE CRETACEOUS ROTATIONAL EVOLUTION OF NEOTETHYAN
SUTURES AROUND ANKARA REGION

A THESIS SUBMITTED TO
THE GRADUATE SCHOOL OF NATURAL AND APPLIED SCIENCES
OF
MIDDLE EAST TECHNICAL UNIVERSITY

BY
MURAT ÖZKAPTAN

IN PARTIAL FULFILLMENT OF THE REQUIREMENTS
FOR
THE DEGREE OF DOCTOR OF PHILOSOPHY
IN
GEOLOGICAL ENGINEERING

JANUARY 2016

Approval of the thesis:

**POST-LATE CRETACEOUS ROTATIONAL EVOLUTION OF
NEOTETHYAN SUTURES AROUND ANKARA REGION**

submitted by **MURAT ÖZKAPTAN** in partial fulfillment of the requirements for
the degree of **Doctor of Philosophy in Geological Engineering Department,**
Middle East Technical University by,

Prof. Dr. Gülbin Dural Ünver

Dean, Graduate School of **Natural and Applied Sciences**

Prof. Dr. Erdin Bozkurt

Head of Department, **Geological Engineering**

Prof. Dr. Nuretdin Kaymakcı

Supervisor, **Geological Engineering Dept., METU**

Assist. Prof. Dr. A. Arda Özacar.

Co-Supervisor, **Geological Engineering Dept., METU**

Examining Committee Members:

Prof. Dr. Erdin Bozkurt

Geological Engineering Dept., METU

Prof. Dr. Nuretdin Kaymakcı

Supervisor, Geological Engineering Dept., METU

Prof. Dr. Kadir Dirik

Geological Engineering Dept., HÜ

Prof. Dr. Hasan Sözbilir

ABSTRACT

POST-LATE CRETACEOUS ROTATIONAL EVOLUTION OF NEOTETHYAN SUTURES AROUND ANKARA REGION

Özkaptan, Murat

Ph.D., Department of Geological Engineering

Supervisor: Prof. Dr. Nuretdin Kaymakcı

Co-Supervisor: Assist. Prof. Dr. A. Arda Özacar

January 2016, 200 pages

The central Anatolia comprises various continental fragments belonging to Laurasia at the north and Gondwana at the south. These amalgamated continental fragments (micro continents) delineated by ophiolitic remnants of Tethyan oceanic lithosphere which were consumed due to ~N to S convergence. Around Haymana Basin the closure of the Neotethys Oceans lead to amalgamation of the Pontides (Laurasian affinity) in the north, Tauride and Kırşehir blocks (Gondwana affinity) in the south. The main purpose of this study is to unravel vertical axis rotations in around Haymana Basin using paleomagnetic tools and its deformation history and kinematics using Anisotropy of Magnetic Susceptibility vectors. In this respect, late Cretaceous to Pliocene infill of the Haymana and adjacent basins namely, Alcı-Orhaniye, Tuz Gölü and Kırıkkale-Bala basins in the central Anatolia are systematically sampled and around ~5000 sedimentary paleomagnetic samples for paleomagnetic purposes from 119 different locations within a 250 km diameter area were collected. Before the demagnetization process, nearly 3000 core specimens were measured for anisotropy of magnetic susceptibility (AMS) to reveal their magnetofabric characteristics.

The paleomagnetic results show, that the region underwent strong clockwise and counterclockwise rotations -even more than 90° in places- resulting the present geometry of the suture zones. Overall Haymana Basin has rotated more than 90° counterclockwise while its northern and south parts and northern part of the Tuz

Gölü Basin rotated approximately 30° clockwise senses, which disagrees with almost all the published paleomagnetic data from the region. The restored orientations, based on the new data indicate that Haymana, Tuz Gölü Basin and the Kırıkkale-Bala Basin which constitutes the SW continuation of the Çankırı Basin were initially oriented in N-S direction prior to Eocene. These results are greatly differing from previously published results from the region which assumes that the İzmir-Ankara-Erzincan Suture Zone was oriented E-W. These imply that almost all of the paleogeographical maps and evolutionary scenarios and models of the region requires major re-thinking and serious revisions.

Keywords: Paleomagnetism, Rotation, anisotropic Magnetic Susceptibility (AMS), Central Anatolia, Haymana Basin, İzmir-Ankara Suture, Intra-Tauride Suture.

İç Anadolu geçmişte iki büyük kıta olan kuzeydeki Lavrasya ve güneydeki Gondvana'nın farklı kıtasal parçalarının birleşmesiyle oluşmuştur. Bu bütünleşik kıtasal bloklar (mikro kıtalar) yaklaşık kuzey-güney yönünde daralma sonucunda Tetis okyanusal litosferininin yitiminden kalan parçalarla çevrelenmiştir. Haymana Havzası ve civarında Noe-Tetis okyanusunun kapanmasıyla kuzeydeki Pontide (Lavrasya'nın parçası) ile güneydeki Toros ve Kırşehir Blokları (Gondvana'nın parçaları) bütünleşmiştir. Bu çalışmanın ana amacı Haymana Havzası ve civarında paleomanyetik yöntemler kullanarak düşey eksen blok rotasyonlarını belirlemek ve anizotropik manyetik duyarlılık (süseptibilite) vektörlerini de kullanarak bölgenin kinematik evrimini ortaya koymaktır. Bu kapsamda Haymana Havzası ve civarındaki havzalardan; Alcı-Orhaniye, Tuzgölü ve Kırıkkale-Bala havza dolgularından geç Kretase – Piliyosen zaman aralığına ait sistematik örnekleme yapılarak yaklaşık 250 km² 'lik bir alanda toplamda 119 farklı lokasyondan 5000 civarında paleomanyetik amaçlı tortul kaya örneği derlenmiştir. Manyetik temizleme (demanyetizasyon) işlemlerinden önce yaklaşık 3000 örnek üzerinde anizotropik manyetik duyarlılık ölçümleri yapılarak manyetofabrik karakteristikleri ortaya konulmuştur.

Paleomanyetik sonuçlar bölgenin saat yönünde ve tersi istikamette yer yer 90°'leri geçen aşırı miktarlarda rotasyona maruz kalarak bölgedeki kenet kuşaklarının günümüzdeki geometrilerini kazanmasına neden olmuştur. Genel olarak Haymana Havzası'nın tamamı 90°'lere yakın miktarlarda saatin tersi yönde rotasyona

uğrarken, Çankırı Havza'sının güneybatı devamını oluşturan Kırıkkale-Bala ve Tuz Gölü Havza'sının kuzey bölümünden oluşan bölge yaklaşık 30° saat yönünde dönmeye maruz kalmıştır. Bu sonuçlar bölgede yapılan daha önceki paleomanyetizma çalışmalarından oldukça fazla farklılık göstermektedir. Bu çalışma sonucunda ortaya çıkan yeni verilere göre bölge restore edildiğinde Haymana, Tuz Gölü, ve Kırıkkale-Bala havzalarının Eosen öncesinde K-G doğrultulu oldukları ortaya çıkmaktadır. Önceki bir çok çalışmanın İzmir-Ankara-Erzincan Kenet Kuşağının yönünün D-B olduğunu farz ettiği dikkate alındığında, bu yeni sonuçlar; literatürde bölge için önerilmiş olan paleocoğrafik haritaların, tektonik evrim senaryoların ve modellerin tekrar gözden geçirilmesini zorunlu kılmaktadır.

Anahtar Kelimeler: Paleomanyetizma, rotasyon, Anizotropik Manyetik Duyarlılık (AMD), Orta Anadolu, Haymana Havzası, İzmir-Ankara Kenedi, Intra-Torid Kenedi.

To all those who take part in this research

ACKNOWLEDGEMENTS

There are many people to thank who have helped me complete this thesis.

First and foremost, I would like to thank to my supervisor Prof. Dr. Nuretdin Kaymakcı, for his guidance and support in every steps of this study. He always standing beside me throughout my career and also improved the scientific content of this thesis.

I would also like to express my deepest gratitude to Prof. Dr. Cor Langereis who thought me paleomagnetic measurement and interpretation techniques. I also would like to him his hospitality, openness, being always ready to help and providing an excellent working environment while I was in Utrecht.

I would like to express my appreciation to my co-supervisor Dr. A. Arda Özacar for his time, support, and his valuable advices.

My Ph.D. committee members, Dr. Erdin Bozkurt, Dr. F. Hasan Sözbilir, Dr. Kadir Dirik and Dr. Erman Özsayın are deeply appreciated for their critical reading and suggestions for improving and increasing the quality of this thesis.

I am indebted to Forth Hoofddijk Paleomagnetic Laboratory team members; especially Mark Dekkers whom patiently thought me how to use paleomagnetic equipment and always provided a pleasant environment and time shifts for the measurements.

I would like to thank to my dear friends Dr. Erhan Gülyüz, Mrs. Nilay Gülyüz, and Abdul Qayyum for company and help during fieldworks. My hard and long field studies could not have been completed without their assistance.

A special thanks to my new sisters Mrs. Pınar Ertepinar Kaymakcı and Öykü Ertepinar for their endless support and Öykü's delicious cooking. Thank you dear.

In Utrecht, thanks to Ahmet Peynircioğlu and Derya Güerer from Utrecht University, the Netherlands, for collaboration and their warm hospitality.

At last but definitely not the least, I am grateful to Mrs. Tuğçe Özvural for her endless help, patience and motivation during my study. Without her company and the bright and practical solutions she provides, this study could not have been completed.

Finally, I would like to express my gratitude to my parents. Without the support of my family, this study would not have been accomplished.

CHAPTER 1

INTRODUCTION

1.1 General

Discovery of the lodestone or loadstone (magnetite) which name was derived from middle English word load, meaning “way” or “course” loadstone was literally a “course stone” that help to travelers and navigators to find their way in ancient times (Lowrie, 2007).

Earth magnetic field, since it's first realized by Chinese navigators, still one of the most magnificent features of the Earth and has been used not only navigation purpose but it is also helps to illuminate solving some significant geological problems which are the first and foremost clear geophysical evidence into the plate tectonics.

Regarding the paleomagnetism, intensity and orientation of earth's past magnetic field is recorded by the help of certain magnetic minerals contained within the sedimentary, igneous and metamorphic rocks that provide information about the characteristics and orientation of the magnetic vector of the earth and how it changed in time. Using this phenomenon the position and rotation amounts of tectonic blocks in different time intervals throughout geological past can be reconstructed (Butler 1998; Tauxe 2010). In general, the paleomagnetism has both geochronological and tectonic applications. The age of a rock can be determined with high precision by correlating it with the established geomagnetic pattern of the earth through time and by obtaining the magnetic declination of a rock and comparing it with respect to present magnetic vector (declination, inclination) provides information about how tectonically the rocks might have been deformed (Susman and Weil 2004) and by the use of paleoinclination values the paleo-latitudinal positions of tectonic blocks can be determined (Tauxe 2010).

Paleomagnetic applications in Turkey dates back to 1960's and after the pioneering work of Vander Voo (1968) which aimed at determination of paleolattitudinal position of Pontide belt during the Mesozoic, a number of paleomagnetic studies have been conducted especially in 1990's most of which are related to fault block rotations related to North Anatolian fault Zone (e.g. Platzman *et al.* 1994; Tatar *et al.*, 1995, 1996; Gürsoy *et al.*, 1997). During this time interval a number of magnetostratigraphical studies have also been conducted (e.g. Gallet *et al.*, 1992, 1993, 1994, 2000; Krijgsman *et al.* 1996). In 2000's the number of paleomagnetic studies have increased significantly and are varied. In this time interval, a number of studies related to tectonic block rotations related to paleotectonic period have also been conducted (e.g. Kaymakcı *et al.* 2003; İşseven *et al.* 2006; Meijers *et al.* 2010; van Hinsbergen 2010a, b; Çinku *et al.* 2011, 2013; Uzel *et al.* 2015; Koç 2016).

The main concern of this thesis is determination of vertical axis block rotations in north central Anatolia along the Izmir-Ankara and Intra-Tauride suture zones which demarcates the former position of the Neotethys Ocean that subducted and obliterated completely by the end of Cretaceous to early Paleogene (Okay *et al.* 1984; Okay and Tüysüz 1999; Kaymakcı *et al.* 2000 & 2009; Pourteau *et al.* 2015). Therefore, the study is concentrated mainly around the Haymana and adjacent basins that include northern continuation of Haymana Basin into the Alcı-Orhaniye sub-basin (Koçyiğit *et al.*, 1988; Koçyiğit 1989; Rojay and Süzen 1997), southwestern continuation of Çankırı Basin around Kırıkkale-Bala region (Kaymakcı *et al.* 2009), and exposed Paleogene sector of the Tuz Gölü Basin (Çemen *et al.* 1999).

1.2. Purpose and scope

The main objective of this study is to determine the amount and timing of vertical axes rotations in Haymana and adjacent basins in order to unravel the evolution of the Izmir-Ankara and Intra-Tauride suture zones in relation to the terminal subduction of the Neotethyan Oceanic lithosphere and subsequent collision of the intervening continental blocks that include Taurides and the Kırşehir Block (*sensu* Görür *et al.* 1984) into the Pontides. The Izmir-Ankara Suture Zone demarcates the former position of the Neotethys Ocean between Pontides in the north and Taurides

and Kırşehir Block in the south while Intra-Tauride Suture Zone separates Taurides from the Kırşehir Block (Görür *et al.*, 1984; Kaymakcı *et al.*, 2009; Pourteau *et al.* 2015, van Hinsbergen *et al.* 2016).

In order to accomplish this purpose, a very detailed and extensive field study and comprehensive sampling strategy have been performed in the study for the time interval extending from the Late Cretaceous to Pliocene. Sampling is performed mainly on the fine grained clastic sedimentary rocks and clayey limestone units as well. During sampling a pseudo magnetostratigraphical sampling strategy was followed so that sampling was performed at different levels of each lithostratigraphical units, in each site, for certain time intervals. The purpose of such sampling strategy was to determine the exact timing of the inception and cessation of rotational deformation (Figure 1.1) in the region. In addition to this, a detailed rock magnetic property analysis has also been performed on each sample, in order to determine variations in the intrinsic versus tectonically induced changes in the magnetic properties of the samples. The obtained results are analyzed and the ones related to tectonic processes are scrutinized accordingly.

Determination of tectonic block rotations and related finite strain tensors by the help of magneto-fabric analysis are very important in terms of understanding the styles and modes of deformation, which in turn provide crucial information about geodynamical evolution in an area.

In summary, the main purpose of this research is to determine vertical-axis block rotations in Haymana and adjacent central Anatolian basins for late Cretaceous to Pliocene period in order to understand the tectonic relationship between Izmir-Ankara-Erzincan and the Intra-Tauride suture zones and their temporal and spatial evolution since the Late Cretaceous. The obtained results are evaluated in relation to the terminal subduction of the Neotethys and collision of intervening continental blocks during the Late Cretaceous to Late Paleogene and to the transcurrent tectonics that has been dominated in much areas of Turkey during the late Neogene and Quaternary.

1.3. Tectonic Setting of the Study area

The study area is located in a zone where İzmir-Ankara and Intra-Tauride suture zones meet in north central Anatolia (Turkey). İzmir-Ankara Suture represents the western sector of the Izmir-Ankara-Erzincan Suture Zone and is the suture between Taurides in the south and Pontides in the north, while the eastern sector demarcates the suture between Pontides in the north and the Kırşehir Block in the east. On the other hand, the Intra-Tauride suture developed between Taurides in the south and southwest and the Kırşehir Block in the east and northeast (Figure 1.1). All of these suture zones demarcate the former position of Neotethys Ocean in Turkey which completely subducted and obliterated at the end of Cretaceous to earliest Paleogene (Kaymakcı *et al.*, 2009; Pourteau *et al.*, 2010, 2013; van Hinsbergen *et al.*, 2016).

The geometry, position and tectonic relationships of different parts of the İzmir-Ankara-Erzincan suture is relatively well known (e.g. Görür *et al.*, 1984; Okay and Tüysüz 1999; Kaymakcı *et al.*, 2009). However, its relationship with the Intra-Tauride suture is relatively unknown and the number of studies that addresses this problem is relatively limited, except for Görür *et al.* (1984) which proposed the existence of Intra-Tauride Suture, Okay and Tüysüz (1999), Pourteau *et al.* (2010 and 2013), van Hinsbergen *et al.* (2016). Understanding of the geometry and tectonic relationship between these suture zones constitutes one of the main objectives of this study.

Figure 1.1. Tectonic setting of the study area. **a)** simplified pre-Neogene tectonic configuration of Turkey, **b)** simplified geological map of north central Anatolia overlaid on shaded topographic relief (adopted from revised 1/500.000 Geological Map of Turkey released in 2003 by Turkish General Directorate of Mineral Research and Exploration).

1.4. Method of study and Data

In order to unravel the tectonic evolution of the study area, it is important that to document deformation history of the basins which record the tectonic events during the deposition of basin infills. This research relies mostly on paleomagnetic analysis of the infill of the central Anatolian Basins (Figure 1.2) and targeted the restoration of the central Anatolian Basins and as well their continental basements during the Upper Cretaceous to Recent development.

For this purpose more than 7000 oriented samples from 119 sites have been collected. The samples were dominantly collected from sedimentary sequences spanning from Upper Cretaceous to Pliocene. Among these collected samples 4500

of them are measured and analyzed in Fort Hoofddijk Paleomagnetic laboratory in Utrecht University, the Netherlands. The remaining samples are stored for further analyses. The analyses of the samples are performed on the basis of the tectonic domain they are collected.

For this purpose, the study area is divided into four basins based on their characteristics and position with respect to the involved tectonic blocks. These basins (Figure 1.1 and 1.2) include **1)** Kırıkkale-Bala Basin: It is located at the interaction zone of Çankırı and Tuz Gölü basins. Kaymakcı *et al.* (2009) argued that it is the SW continuation of Çankırı Basin. Since its basement is constituted by Kırşehir Block and thrust over from the north by the Pontide related units. It also comprises mainly similar lithologies with the Çankırı Basin and related to the development of the Ankara-Erzincan Suture Zone. **2)** Tuz Gölü Basin: It straddles the Kırşehir Block in the east and Taurides in the west therefore it is related to the development of the Intra-Tauride Suture zone. **3)** Haymana Basin: it straddles the İzmir-Ankara Suture Zone where Pontides thrust over the Taurides from north to south. The basement of Haymana Basin is constituted mainly by Late Cretaceous ophiolitic mélangé and its southern boundary with the Taurides is obscured by Neogene cover. **4)** Alcı-Orhaniye Basin is developed mainly on the Pontides and connects the Haymana Basin to the Mudurnu-Alcı Basin (Figure 1.2).

Figure 1.2. Correlation of stratigraphy of central Anatolian basins.

1.5 Stratigraphy of Study Area

The stratigraphy of the study area is represented by the Haymana basin which has the most complete and the thickest exposed stratigraphy among the sampled basins. The basin stratigraphy is established mainly by Ünal (1976) and almost all other younger studies followed the stratigraphical scheme of him. The Haymana Basin developed mainly on the Late Cretaceous ophiolitic mélangé related to subduction of the Neotethys Ocean if not on the Sakarya Continent. The basement of the basin is constituted by lithologies belonging to basement of the Sakarya Continent represented by pre-Triassic metamorphic rocks, Triassic slightly metamorphosed blocky mélangé of Karakaya Complex and Mesozoic mainly carbonate dominated cover rocks that unconformably overlie the basement of the Sakarya Complex (Figure 1.3) (Koçyiğit *et al.*, 1988; Koçyiğit 1989).

According to Ünal (1976) the infill of the Haymana basin comprises five stratigraphical cycles. The oldest cycle in the basins comprises Haymana and

Beyobası formations. Haymana Formation comprises mainly alternation of turbiditic sandstone, siltstone, shale and marl. The base of the formation can be observed around Haymana and in the southern part of the basin.

At the base it is characterized by boulder to block sized conglomerates which very rapidly fines and thins upwards. The thickness of these very coarse clastics reaches up to 10 m around Hayman and may reach to 30 m in the southern part of the basin. The boundary between Haymana and Beyobası formation is gradational and Beyobası Formation is characterized relatively thinner and distal turbiditic facies dominated by sandstone, sandy marl and organic rich layers with occasional thin coal seams (Figure 1.3).

The second cycle in the basin infill comprises laterally and vertically grading Kartal, Çaldağ and Yeşilyurt formations. Kartal Formation composed mainly of continental red beds while Çaldağ Formation comprises mainly of neritic carbonates dominated by reefal limestones and Yeşilyurt Formation comprises mainly distal fine clastics dominated by marls. These units conformably overlies the Late Cretaceous units and are of Paleocene in age (Ünalán 1976).

The third cycle in the basin fill comprises relatively carbonate dominated proximal Kırkkavak Formation which laterally and vertically grades into Ilgınlıkdere Formation of medial to distal turbidites dominated by sandstone, siltstone and shale. It grades vertically into Eskipolatlı Formation which is composed of medial to distal turbidites intercalated with nummulites bearing marls and limestones. The age of the third cycle rocks span from Late Palaeocene to Middle Eocene according to fossil fauna they contain (Ünalán *et al.* 1976, Prof.Dr. Ercan Özcan of Istanbul Technical University, personal communication 2014).

The fourth cycle comprises Beldede, Çayraz and Yamak formations. Although the boundary between third and fourth cycles is gradational in most parts of the Haymana Basin, However, around 5 km north of Haymana a local angular unconformities separates Çayraz Formation from the underlying second cycle units. Beldede Formation comprises mainly continental red clastics while Çayraz Formation is characterized by nummulitic limestones and Yamak Formation

comprises alternation of conglomerates, sandstones, shale and marl of turbiditic origin.

The fifth cycle comprises Neogene cover rocks. These units are generally characterized by fluvio-lacustrine associations. They are not bound to Haymana or any other basins in the study area and belong to tectonic regimes that postdate Late Cretaceous to Early Miocene subduction and subsequent collisional convergence (Kaymakci *et al.* 2009, Gülyüz 2015).

System	Series	Thickness (m)	Description		Cycle
Quaternary				Alluvium	5 Cover
Neogene	Mio-Pliocene	400		Cihanbeyli Fm: red beds and evaporites	
Paleogene	Eocene	5000		ANGULAR UNCONFORMITY	4
				Yamak Fm: conglomerate,sandstone,mudstone	
				Çayraz Fm: limestone and marl	
			Beldede Fm: continental red clastics	3	
			LOCAL UNCONFORMITY		
			Eskipolatli Fm. mainly medial to distal turbidites		
Paleocene			Ilginkidere Fm. Mainly proximal top medial turbidites	2	
		Kirkkavak Fm. Mainly algal limestone and marl and calciturbidites			
		Y: Yesilyurt Fm. Marl dominated			
		2 Çaldag Fm. Reefal limestone dominated			
Cretaceous	U. Cretaceous		1- Kartal Fm. Continental red clastics	1	
			Beyobasi Fm. mainly sandstone,sandy marl and organic rich layers and coal		
			Haymana Fm. Dominated by shale and turbiditic sandstone		
Mesozoic				UNCONFORMITY Mollaresul Fm. Mesozoic cover of Sakarya Continent (mainly carbonates)	Basement
Permo-Trias.				UNCONFORMITY Imbrication of pre-Triassic Metamorphics and Triassic Karakaya Complex (Basement of Sakarya Continent)

CHAPTER 2

ANISOTROPIC MAGNETIC SUSCEPTIBILITY: DETERMINATION OF PRINCIPAL STRAIN DIRECTIONS IN THE CENTRAL ANATOLIA

2.1. Introduction

The Anisotropy of Magnetic Susceptibility (AMS) is often determined by directional variances of induced magnetization strength properties of a rock sample when measuring in different directions within the certain amount of applied magnetic field (Owens and Bamford, 1976; Hrouda, 1982; Borradaile, 1988). It delineates preferred orientation of the magnetic properties (susceptibility) of minerals within a rock unit. In spite of the fact that the initial systematic background was introduced by Voight and Kinoshita (1907), the first applications of AMS as a petro-fabric marker was investigated by Ising (1942), who realized that magnetic susceptibility increase as the measurement orientation become perpendicular to the bedding plane which has the minimum Eigen values (Schmidt 2007). Graham (1966) proposed that the AMS is related to the finite strain and could be used as a strain marker in the deformed rocks. In the following years, increasing number of AMS studies, carried out on various rock types to unconsolidated loose sediments, progressively populated the literature. Some of the most notable of these studies include Fuller (1964), Hrouda & Janák (1976), Kneen (1976), Kligfield *et al.* (1977), Hrouda (1982), Tarling and Hrouda (1993), and Duermeijer *et al.* (1998). Following these studies AMS became a standard tool for determination of strain ellipsoid in the rocks.

The AMS technique can be used in nearly all types of rocks, even in the case of absence of lineation and foliation and provides non-destructive, fast, accurate and inexpensive way to determine the petro-fabric characteristics of minerals and their preferred orientations within a rock. The principal directions of anisotropy in the rocks are generally related to orientation of folds, faults, foliations and lineations of the rock units (Hrouda and Janak 1976, Borradaile 1988; Averbuch *et al.* 1992, Robion *et al.*

2007; Borradaile and Jackson 2010). Although the technique has great advantages, however, it has inherited complications since the AMS results are the combination of factor(s) that include mineral physical properties, crystal structure, mixture of mineral compositions, tectonic and metamorphic processes such as current directions from sediments, flow-directions from magma, finite-strain directions from tectonized rocks and stress-orientations from low-strain, low-temperature, environments, etc. (Borradaile and Henry 1997; Borradaile and Jackson 2004). In order to obtain an accurate correct understanding of the AMS results, all of these variables needed to be taken into consideration.

The anisotropy of magnetic susceptibility (AMS) technique as a paleomagnetic tool has been increasingly applied on wide range of application in geology since last decades. The weakly deformed sedimentary rocks under a contractional regime orient its minimum susceptibility axis ($k_{\min}$) perpendicular to the bedding plane or maximum susceptibility axis ($k_{\max}$) perpendicular to the direction of main shortening axis, parallel to fold axis, thrust faults, and local bedding strike (Lee *et al.*, 1990; Tarling and Hrouda 1993). However under the extensional regime, the maximum susceptibility axis aligns perpendicular to normal faults and parallel to bedding dip direction. Increasing the intensity of extensional deformation converts the susceptibility ellipsoid to have more prolate geometry (Lee *et al.*, 1990; Tarling and Hrouda, 1993) than oblate and finally become triaxial in shape.

In this regard, the AMS technique is successfully applied to the infill of the Haymana and adjacent basins within the study area. The analyses have shown that the technique has merits and produced compatible results with the large scale structures in the study area.

2.2. Sampling

In three years of field work, we carried out a very comprehensive paleomagnetic sampling in the central Anatolia (Turkey). More than 3000 cylindrical cores with 1'' (2.54 cm) diameter and more than 2'' (>5 cm) length (oriented cores) have been collected from 110 sites. The samples were collected from rock units ranging in age from late Cretaceous to Pliocene. Most of the samples were collected largely from

sedimentary rocks, although volcanic rock samples were also collected in places (Figure 2.1 and 2.2; Table 2.1).

In general, dominantly clayey, thinly bedded fine grained lithologies were sampled. For each site, at least 15 oriented cores were collected that is distributed within approximately 15-20 meters in stratigraphic thickness, in order to avoid possible paleo-secular variation effect.

The samples were collected using a portative gasoline powered motor drill and an electrical drill with generator, based on the ease of drillability of the rock units. Since the length of a single core was longer than 2", they often provided multiple specimens on which various measurement techniques were applied on the same sample. Consequently, the amount of measured specimens are higher than the number of sampled cores. Core orientations (drilling position) and bedding attitude were measured by using a magnetic compass. The present day declination value for the study area is 4.5° (to the east) (<http://www.ngdc.noaa.gov/geomag-web/#declination>, National Oceanic and Atmospheric Administration, last visited on January 2016) during the time of sampling and each sample was corrected according to this value.

2.3. Measurement and Analysis

The laboratory analyses were conducted at the Forth Hoofddijk paleomagnetic laboratory at the Utrecht University (Utrecht, the Netherlands). All the samples were cut in to the standard paleomagnetic measurement size (2.54 cm diameter and 1.3 cm height). The specimens were measured an automatic field variations (low field, 200 A/m) using the Multi-Function Kappabridge MFK1-FA (AGICO-Brno, Czech Republic) equipped with an up-down mechanism and a rotator. The sensitivity is 10^{-8} SI which is critical to measurement in weak magnetic carries of the carbonate rocks. The measurement was operated by rotation of the specimen in three perpendicular plane positions while the magnetic moment in the applied field monitored following the spinning specimen method. This gives an opportunity for computing the principal susceptibility axes of an AMS ellipsoid following the procedure introduced by Jelinek (1997).

Lat: Latitude, **Long:** Longitude, **N_{AMS}:** number of measured specimens; **km(SI)**=($k_{\max}+k_{\text{int}}+k_{\min}$)/3 mean susceptibility; **L**= $k_{\max}/k_{\text{int}}$ (magnetic lineation); **F**= $k_{\text{int}}/k_{\min}$ (magnetic foliation); **P_j**= $\exp\sqrt{2}[(n1-n)^2+(n2-n)^2+(n3-n)^2]$, degree of anisotropy (corrected) (Jelinek, 1981); **T**= $2\ln(k_{\text{int}}/k_{\min})/\ln(k_{\max}/k_{\min})-1$, shape parameter (Jelinek, 1981); **D/I**= declination/inclination of the principal susceptibilities after tilt correction; **kmax/kmin:** maximum/minimum normed principal susceptibility values; **e:** semi-angle of the 95% confidence ellipse around the $k_{\max}$ axis in three planes ($k_{\max}$ - k_{int} , k_{int} - $k_{\min}$, $k_{\max}$ - $k_{\min}$). $n1 = \ln k_{\max}$, $n2 = \ln k_{\text{int}}$, $n3 = \ln k_{\min}$, $n = (n1 + n2 + n3)/3$.

Figure 2.2 Blow-up map of the Haymana Basin area showing the location of sampling sites.

During the measurements, the specimen was rotated subsequently about three perpendicular plane positions for anisotropy and one for the bulk susceptibility as dictated by the spinning specimen measurement method. Between these steps, the bridge was zeroed before inserting the specimen in to the measuring coil. So, differences between the steps were determined more precisely and susceptibility

tensor enhanced from the measurement on the lowest possible, therefore most sensitive range. Herewith, with combining of four values a complete susceptibility tensor was calculated.

Most of the rocks have mix of minerals with ferromagnetic, paramagnetic or diamagnetic properties which ranges from negative values (10^{-5} SI) for diamagnetic, to positive values but low in paramagnetic (10^{-4} - 10^{-5} SI) and high in ferromagnetic ($\geq 10^{-4}$ SI) (Nagata, 1961).

Generally, sedimentary sequences show low susceptibility ($< 10^{-4}$ SI) and anisotropy ($< 5\%$) values. The results for each specimen can be enhanced due to a variety of mineral composition in the rocks.

The AMS susceptibility or deformation ellipsoid is defined by three principal axes; $k_{max} \geq k_{int} \geq k_{min}$ namely maximum, intermediate, and minimum susceptibility values per specimen, respectively. The shape of the magnetic susceptibility ellipsoid corresponds to these strain axes. When the k_{min} smaller than k_{max} , k_{int} , the shape of the AMS ellipsoid become oblate and k_{min} clustering perpendicular to the bedding plane, k_{int} & k_{max} scattering parallel to the bedding plane that is the in common in sedimentary rocks. Increasing the deformation range and other dynamic effects (i.e. paleocurrent), oblate shape transforms into prolate and k_{min} axis is not perpendicular to the bedding plane, while parallel to the strike indicate maximum extension direction or perpendicular to the maximum principal stress direction in weakly deformed sedimentary units. There are great variety of parameters that have been used to qualify susceptibility magnitude and the other shape features. Some are given at below as an example;

P_j = corrected degree of AMS, $\exp \{2[(n_1 - n)^2 + (n_2 - n)^2 + (n_3 - n)^2]\}^{1/2}$

L: magnetic lineation, $= k_{min}/k_{int}$

F: magnetic foliation, $= k_{int}/k_{min}$

T: shape parameter, $“(2n_2 - n_1 - n_3)/(n_1 - n_3)”$

Where, $n_1 = \ln k_1$, $n_2 = \ln k_2$, $n_3 = \ln k_3$, $n = (n_1 + n_2 + n_3)/3$, proposed by Jelinek (1981).

km: the mean magnetic susceptibility (km) is calculated as $km = (k_1 + k_2 + k_3)/3$ (Nagata, 1961), and is related to the qualitative and quantitative content of magnetic mineral composition in a rock. The mean magnetic susceptibility to express the fabric intensity as a measure of eccentricity,

Pj indicates the intensity of preferred orientation of the magnetic lineations in a rock, T gives information about to the shape of the susceptibility ellipsoid that the value varies in between -1 to 1 responsible for an oblate to prolate ellipsoid shape, respectively.

All the data are converted first to specimen coordinate system to geographic orientations, similarly the same concept is followed for tilt (bedding) correction (also known as tectonic correction-TC). The results, from both, each specimen and the site means, were obtained by applying Jelinek statistics (1977, 1978) and are illustrated by Anisoft 4.2 program (Chadima and Jelinek, 2009).

2.4. Magnetofabric characteristic

Before the interpretation of the AMS lineament results, magnetic mineralogical properties (e.g. anisotropy degree, bulk susceptibility) and their shape parameters (magnetic foliations and lineations) are analyzed for the sites. All the results from 106 sites analyzed based on their age and separated into five age groups; **1)** the first group comprises 13 late Cretaceous sites, **2)** the second group includes 31 Paleocene sites, **3)** Eocene to Oligocene sites number is 31, **4)** for Miocene total number of 21 sites, and **5)** the last group includes 9 Pliocene sites. These sites collected from four sub areas which include; Haymana, Tuz Gölü, Kırıkkale-Bala, and the Alci-Orhaniye basins.

2.4.1. Late Cretaceous sites

The study area is represented by 16 Upper Cretaceous sedimentary AMS sites. The sites mainly composed of alternation of yellowish to reddish and brown to greenish sandstone-mudstone alternations. The mean magnetic susceptibility (km) of all sites ranging from 78.6×10^{-6} SI to 1980×10^{-6} SI indicating a major contribution of the paramagnetic to small percentage of ferromagnetic constituent minerals of the rocks

to the bulk susceptibility results (Rochette, 1987; Sagnotti *et al.*, 1998) (Figure 2.3; Table 2.1).

The results from various lithologies indicated that the magnetic susceptibility magnitudes controlled by the nature of the rocks. The site degrees of corrected anisotropy (P_j) values relatively low (<1.1) and the specimen results varies in wide range from 1.008 to 1.175 indicate only poorly developed magnetic fabric (Figure 2.3; Table 2.1). The shape of the anisotropy ellipsoids ranges from prolate ($T < 0$ and $L > F$; SEC3) to neutral ($T \sim 0$ and $L/F \sim 1$; RY1, RH1, R73, R 65) and rest of them strong oblate ($T > 0$ and $F > L$) (Table 2.1).

In the Figure 2.3; the last diagram illustrates distribution of sum of results of mean magnetic susceptibility and Jelinek (T versus P_j) results in 16 sites. The results show both prolate and oblate in shape.

2.4.2. Paleocene Sites

31 Paleocene sites were analyzed for rock magnetic properties in the study area. The susceptibility and Jelinek diagrams for Paleocene sites are depicted in Figure 2.4. The 31 Paleocene sites contain samples collected only from sedimentary rocks that include limestone and clastic rocks (red to green mudstone-sandstone and claystone). Rock magnetic properties of these samples are closely connected with their position and matrix ingredients and there is no relationship with their ages. The site mean susceptibility values range between a minimum of -9.25×10^{-6} SI and maximum of 7820×10^{-6} SI indicating three types of magnetic contributions; diamagnetic from limestone (R20, R34, RN10), paramagnetic and ferromagnetic dominant minerals in the rest (Table 2.1).

The shape parameters indicate that the anisotropy ellipsoids change from prolate ($T < 0$ and $L > F$; R20, R 43, R 59, R60, RN10, RN11, and RN12) to neutral ($T \sim 0$ and $L/F \sim 1$; R11, R34, R36, R74, RN2) and rest of them show strong oblate geometry ($T > 0$ and $F > L$) (Table 2.1).

As seen in the combined results of the sites (the last plot in the Figure 2.4), P_{mean} susceptibility (k_m) and corrected anisotropy degree varies in wide range. In addition, the resultant shape parameters indicate the variation both from prolate to oblate.

(Figure 2.3 continued)

Figure 2.4. Magneto-fabric parameters of 31 Palaeocene sites and the combined result. The site mean shape parameter (T) vs. corrected anisotropy degree (P_j) plot (Jelinek Diagram) is on the right, the corrected anisotropy degree (P_j) vs. magnetic bulk susceptibility (km) plot is on the left. Oblate susceptibility ellipsoids fall in the $T > 0$ and $F > L$ domain, while prolate susceptibility ellipsoids are in the $T < 0$ and $L > F$ domain.

Oblate susceptibility ellipsoids fall in the $T > 0$ and $F > L$ domain, while prolate susceptibility ellipsoids are in the $T < 0$ and $L > F$ domain.

(Figure 2.5 continued)

(Figure 2.5 continued)

(Figure 2.5 continued)

2.4.3. Eocene-Oligocene sites

The Eocene-Oligocene rocks composed of sandstone-claystone-mudstone alternations intercalated with various carbonate rocks. The 31 sampling sites distributed relatively homogeneously in the study area unlike sites belong to other sampled time intervals (Figure 2.1 and 2.2). The magnetic property analysis results show that they are controlled by the position of the sampling site. The km (SI) values are swinging between negative values which indicate diamagnetic properties (e.g. R63) to moderate values ranging between $\sim 90 \times 10^{-6} - 1500 \times 10^{-6}$ (SI) and very high values that exceed >1500 SI. They indicate ferromagnetic minerals that dominate most of Eocene-Oligocene samples (Figure 2.5; Table 2.1).

The shape parameters show AMS ellipsoids from prolate ($T < 0$ and $L > F$) to neutral ($T \sim 0$ and $L/F \sim 1$) and strong oblate geometry ($T > 0$ and $F > L$) (Table 2.1). The last diagrams in the Figure 2.5 illustrate combined results of all Eocene-Oligocene sites.

2.4.4. Miocene sites

Miocene is represented by 21 sites (Figure 2.6; Table 2.1.) The k_m values are generally lower in the carbonate rocks (Figure 2.6; Table 2.1). Interestingly there are no negative (diamagnetic) mean susceptibility results in the measurements. On the other hand, the volcanic rocks (e.g. R13, R 45, and R46) produced very high mean susceptibility values (11500-42600 SI) clearly indicating their volcanic origin.

The AMS ellipsoids of Miocene sites are oblate to neutral and only few sites produced neutral to prolate shapes (R3, R37, and R50).

2.4.5. Pliocene sites

For Pliocene time interval only 9 AMS results are available. The sites generally distributed in the southern part of the study area (Figure 2.1 and 2.2). Almost all of the samples belongs to lacustrine deposits. They are composed of fine grained clastics such as siltstone and mudstone, and marl alternations. Likewise other sedimentary rock samples their mean magnetic susceptibility values are relatively low compare to older rocks (Eocene and older) (Table 2.1). The k_m values change between 2.85 to 5670 SI. Similar to the Miocene sites, there is no negative (diamagnetic) susceptibility values, possibly due to the contribution of Miocene and younger volcanism in the region.

The magnetic susceptibility magnitude values changes according to the lithology in each sites. The results of corrected anisotropy (P_j) values relatively low (<1.05 , except for the site SF3 which has 1.02). This implies low degree of deformation and indicate poorly developed magnetic fabric possibly related to tectonic deformation (Figure 2.7; Table 2.1). The AMS ellipsoids dominantly have oblate shape ($T>0$ and $F>L$; R27, R50, R51) to neutral ($T\sim 0$ and $L/F\sim 1$; R37, SF3, SF4) and rest of them have mixed geometries (Figure 2.7 and Table 2.1).

The site means shape parameter (T) vs. corrected anisotropy degree (P_j) plots (Jelinek Diagram) on the right, the corrected anisotropy degree (P_j) vs. magnetic bulk susceptibility (km) plot on the left. Oblate susceptibility ellipsoids fall in the $T > 0$ and $F > L$ domain, while prolate susceptibility ellipsoids are in the $T < 0$ and $L > F$ domain.

2.5. Evaluation of the AMS results

The anisotropy of magnetic susceptibility results show that the magnetic lineations are sensitive indicators of progressive deformation in the study area. They can be used to differentiate the stages of deformation in the sedimentary rocks. In the study are the obtained results can be categorized in three deformation stages with increasing in the intensity of the tectonic deformation from primary sedimentary fabric (depositional anisotropy) to cleavage development (intense deformation). Theoretically, the stages of deformation related magnetic lineations are as follows;

- ✓ The first case includes the no deformation phase. In this case the minimum susceptibility axis ($k_{\min}$) is perpendicular to the bedding plane and is related to the compaction of the unconsolidated sediments. In this case, the maximum and intermediate susceptibility axes ($k_{\max}$ and k_{int}) are not constrained and therefore they form a girdle distribution, characteristics of an oblate susceptibility ellipsoid.
- ✓ The second case is the intermediate tectonic deformation phase. In this case, $k_{\max}$ is well constrained and parallel to the extension direction while k_{int} and $k_{\min}$ makes a pencil structure perpendicular to $k_{\max}$. The shape of the anisotropy ellipsoid transform from oblate to prolate geometry.
- ✓ The final stage determines full tectonic deformation phase and cleavage structures occur. The minimum susceptibility axis changes into a well-defined cluster that is almost parallel to the bedding plane or normal to the cleavage plane (minimum strain axis), while k_{int} and $k_{\max}$ are fairly clustered. Cleavages can be developed in the specimens at final stage.

The constructed AMS ellipsoids in the study indicate typical of weakly to intermediate deformation phases. The AMS ellipsoid patterns changes from region to region and are independent from the age and lithological characteristics imply tectonic origin for the ellipsoids.

In this section, 106 Upper Cretaceous to Pliocene AMS sites are analyzed from the four basins in the study area namely Alcı-Orhaniye, Kırıkkale-Bala, Tuz Gölü and

Haymana basins (Figure 2.1, 2.2). The k_{max} (also named as AMS lineament) results are presented before and after tilt correction, for five time intervals that include 1) late Cretaceous, 2) Paleocene, 3) Eocene-Oligocene, 4) Miocene, 5) Pliocene.

2.5.1 Late Cretaceous AMS Results

The late Cretaceous results are well clustered in all directions parallel to k_{max} , k_{int} , k_{min} . However, the orientations of the AMS lineaments vary basin to basin. The k_{max} results from site R65 and R67 are almost parallel and indicate NE-SW direction of maximum susceptibility in the Kırıkkale-Bala Basin. They are almost parallel with the bedding strike at the sites. In the site R73, the k_{max} is oriented NW-SE almost perpendicular to the bedding strike and also to the results of the sites R65 and R67 (Figure 2.8).

In the Tuz Gölü Basin the only Upper Cretaceous site (R83) indicate NE-SW oriented k_{max} and it is perpendicular to the bedding strike and the long axis of the basin (NW-SE) which is controlled in its eastern margin by the NW-SE trending Tuzgölü Fault (Figure 2.8).

Similarly, Alcı-Orhaniye Basin is also represented by only one site (R6). The orientation of the k_{max} is NNW-SSE before and after tilt correction and the result not pairing with the site bedding attitude which is NE-SW striking (Table 2.1).

The rest of 9 sites from the Haymana Basin can be divided in two part according to k_{max} lineaments. The first group comprise the sites R21 and R55 which are located NW of the Haymana Basin near the Temelli (Figure 2.8 and 2.9). The results show NNW to NW and SSW to SW k_{max} directions considerably matching with the local bedding strikes of the sites (Figure 2.9)

In the central of the Haymana Basin, from 7 sites indicate more or less E-W direction of k_{max} results which are also perfectly fit to the bedding strikes of the sites (Figure 2.9).

2.5.2 Paleocene AMS Results

The Paleocene sites are not present in all basins. For example, the Paleocene sites in the Tuzgölü basin did not produce and appreciable results and only two sites in the Alcı-Orhaniye Basin produced interpretable results (Figure 2.10).

In the Kırıkkale-Bala Basin, the AMS k_{max} directions gradually changes from almost N-S to NW then to E-W from north to south. At the transition zone from Kırıkkale-Bala to Tuzgölü basins, the K_{max} orientations become E-W (Figure 2.10).

The two sites (R1, R2) in the Alcı-Orhaniye Basin have parallel k_{max} orientation and are oriented NNW-SSE. They are also parallel to the northern part of the Kırıkkale-Bala Basin (Figure 2.10). In these sites the k_{max} directions and the bedding strikes are not parallel to each other neither before nor after tilt correction (Table 2.1).

In the Haymana Basin, mainly two groups of k_{max} orientations can be discriminated. The first group has NW-SE orientation while the second group is oriented NE-SW. The NW-SE striking sites are approximately parallel to the Upper Cretaceous sites and are located mainly at the northwestern part of the basin. The other group located mainly at the central part of the basin and the Paleocene and late Cretaceous orientations are normal to each other (compare Figures 2.10 and 2.11). The second group is positioned at the central part of the Haymana Basin and indicates dominantly E-W k_{max} directions (Figure 2.11).

2.5.3 Eocene-Oligocene AMS Results

Eocene-Oligocene is represented by 31 sites and are relatively well distributed in the study area (Figure 2.12). The AMS susceptibility directions have moderate to low degree of error margins in three directions (Table 2.1).

In the Kırıkkale-Bala Basin two sets of K_{max} directions are determined from four Eocene-Oligocene sites. The first set is compatible with the general orientation of bedding strikes and folds in the basin. They are oriented NE-SW. The second set of AMS data gives NW-SE k_{max} directions which are normal to the first set. Whereas they are parallel to the local (site) bedding strikes (Figure 2.12).

Figure 2.8. Map showing late Cretaceous $k_{\max}$ orientations, in-situ and after tectonic correction, and the strike of the bedding planes at the site. The circles outside the map are distributions of magnetic susceptibility directions; $k_{\max}$ (blue square), k_{int} (green triangle), and $k_{\min}$ (purple circle) (equal area, lower hemisphere projection). Red dashed box is the coverage area of Figure 2.8.

Figure 2.9. Blow up view of the Haymana Basin (see Figure 2.8 for its location) showing late Cretaceous $k_{\max}$ orientations, in-situ and after tectonic correction, and the strike of the bedding planes at the site. The circles outside the map are distributions of magnetic susceptibility directions; $k_{\max}$ (blue square), k_{int} (green triangle), and $k_{\min}$ (purple circle) (equal area, lower hemisphere projection).

Three sites are produced reliable results from the Alcı-Orhaniye Basin. They are very consistent with each other and also with the bedding strikes (Figure 2.12). The tilt corrected $k_{\max}$ directions are oriented NE-SW. Except one site (S8), the $k_{\max}$ results before and after tilt corrections are the same in other two sites.

A large number of Eocene sites are there for the Haymana Basin (Figure 2.13). The AMS $k_{\max}$ are oriented generally E-W direction except few sites which are oriented NE-SW (Table 2.1). The most striking characteristics of the Kmax orientations in the Haymana Basin is that almost all of the sites they follow approximately the local fold trends. As the fold axis deviates from linear and become curvilinear, the $k_{\max}$ orientations also deviates from general trend and become parallel to the folds axis (Figure 2.12 and Table 2.1).

Figure 2.10. Map showing Paleocene $k_{\max}$ orientations, in-situ and after tectonic correction, and the strike of the bedding planes at the site. The circles outside the map are distributions of magnetic susceptibility directions; $k_{\max}$ (blue square), k_{int} (green triangle), and $k_{\min}$ (purple circle) (equal area, lower hemisphere projection). Red dashed box is the coverage area of Figure 2.10.

Blow up map of the Haymana Basin (see Figure 2.10 for its location) showing Paleocene k_{max} orientations, in-situ and after tectonic correction, and the strike of the bedding planes at the site. The circles outside the map are distributions magnetic susceptibility directions; k_{max} (blue square), k_{int} (green triangle), and k_{min} (purple circle) (equal area, lower hemisphere projection).

Figure 2.12. Map showing Eocene-Oligocene $k_{\max}$ orientations, in-situ and after tectonic correction, and the strike of the bedding planes at the site. The circles outside the map are distributions of magnetic susceptibility directions; $k_{\max}$ (blue square), k_{int} (green triangle), and $k_{\min}$ (purple circle) (equal area, lower hemisphere projection). Red dashed box is the coverage area of Figure

2.5.4 Miocene AMS Results

The Miocene sites have high error margins in all AMS axes and are sparsely clustered on the equal area diagrams (Table 2.1; Figure 2.14). The $k_{\max}$ orientations show almost random direction patterns and they do not indicate a common direction on the regional scale (Figure 2.14). The Kırıkkale-Bala and Tuz Gölü Basins do not have Miocene results. The Alcı-Orhaniye Basin has four sites with reliable results and they indicate NE-SW to NW-SE $K_{\max}$ orientations. The $k_{\max}$ directions are highly oblique to almost perpendicular to the bedding strikes. The $k_{\max}$ orientations in the northwestern part of the Haymana Basin near Temelli aligned in NW-SE directions similar to the orientations of older units. However, two sites near Polatlı (west of the Haymana Basin) $k_{\max}$ directions are oriented E-W (Figure 2.14 and 2.15) and in the eastern part of the Haymana Basin they become NE-SW. On the other hand, $k_{\max}$ orientation at the southernmost part of the Haymana Basin indicates roughly N-S directions.

2.5.5 Pliocene AMS Results

AMS results from only 9 sites represent the Pliocene of the study area. 8 of them belong to Haymana Basin and only one site belongs to Alcı-Orhaniye Basin. Kırıkkale-Bala and Tuzgölü basins do not have Pliocene AMS results. $K_{\max}$ in almost all sites (R3, R24, R27, R37, R51, SF4) are oriented about NNW-SSE to NNE-SSW directions except for R32 which is oriented almost ENE-WSW and two other sites (SF3 and R28) which are oriented NW-SE. In most of the sites, the bedding is almost horizontal if not bedding strike and $K_{\max}$ are oblique to each other (Figure 2.16 and 2.17; Table 2.1).

Figure 2.14. Map showing Miocene k_{max} orientations, in-situ and after tectonic correction, and the strike of the bedding planes at the site. The circles outside the map are distributions of magnetic susceptibility directions; k_{max} (blue square), k_{int} (green triangle), and k_{min} (purple circle) (equal area, lower hemisphere projection). Red dashed box is the coverage area of Figure 2.15.

The circles outside the map are distributions magnetic susceptibility directions; kmax (blue square), kint (green triangle), and kmin (purple circle) (equal area, lower hemisphere projection).

2.5. Discussion

2.5.1. Tectonic Implications of AMS Results

The average AMS vectors for each basin for different time intervals is depicted Figure 2.18. As seen in the figure the late Cretaceous maximum susceptibility vectors ($k_{\max}$) are almost parallel to the margin of the Kırıkkale-Bala while the intermediate susceptibility vector (K_{int}) is perpendicular to the basin margin. However, in Alcı-Orhaniye basin $K_{\max}$ vectors are parallel to the basin margin while

K_{int} vectors are perpendicular. In Haymana basin the K_{max} vector is almost E-W and parallel to the major structures (folding) while K_{int} vector is N-S and perpendicular to the major structures in the basin. In Tuzgölü basin the K_{max} is perpendicular to the Tuzgölü Fault while K_{int} is parallel to the fault.

In all basins the K_{min} is perpendicular to the bedding plane hence it is related to the compaction of the basin infill. Therefore, the other AMS vectors (K_{int} and K_{max}) are related to tectonic deformation in the study area. In this case, K_{int} is thought to be parallel to maximum contraction while K_{max} is parallel to the maximum extension (stretching). Based on this assumption, during the late Cretaceous, Kırıkkale-Bala and Tuzgölü basins were subjected to NW-SE contraction while Alcı-Orhaniye Basin was subjected to extension in the same direction (NW-SE) and Haymana basin was subjected to N-S contraction and E-W extension.

For Palaeocene time interval there is no information from the Tuzgölü Basin but all other basins were subjected to NE-SW contraction and NW-SE extension.

During the Eo-Oligocene time interval Kırıkkale-Bala and Alcı-Orhaniye basins were subjected to NE-SW extension and NW-SE contraction, while Haymana Basin was subjected to NNE-SSW contraction almost like in Palaeocene and late Cretaceous, however Tuzgölü basin was subjected to NE-SW contraction perpendicular to Tuzgölü Fault.

During the Miocene and Pliocene, the K_{max} and K_{int} (extension and contraction) directions are almost parallel, the only difference took place in the western part of Haymana Basin where N-S compression in the Miocene is replaced by E-W compression. The orientation of extension and contraction directions for Miocene and Pliocene in the Alcı-Orhaniye basin is NW-SE and NE-SW respectively. The central eastern part of Haymana basin is characterized by WNW-ESE compression and ENE-WSW extension for both Miocene and Pliocene time intervals. Kırıkkale-Bala basin only has data for the Miocene time interval and it is parallel to the central and eastern part of the Haymana basin which is characterized by NE-SW extension and NW-SE contraction.

2.6. Conclusions

Analysis of AMS data from 106 sites provided important clues about the deformation styles and major strain directions in the study area since late Cretaceous. Beware that all the interpretations were based on present geographic orientations. No back rotation has been performed for clarity.

The main conclusions of this chapter are as follows;

1. Most of the AMS results are originated from tectonic deformation except for $k_{\min}$ which is almost vertical due to compaction of sedimentary rocks.
2. There is a very prominent boundary that separates the domains with similar AMS vector orientations. This boundary corresponds to Dereköy-Hirfanlı Fault Zone.
3. During the late Cretaceous Tuz Gölü and Kırıkkale-Bala basins was subjected to NE-SW extension and NW-SE contraction while Hayman Basin was subjected to NS-contraction and E-W extension. In the same time Alcı-Orhaniye Basin was subjected to NW-SE extension and NE-SW contraction.
4. Most of the AMS results are originated from tectonic deformation except for $K_{\min}$ which is almost always due to compaction of sedimentary rocks.
5. There is a very prominent boundary that separate the domains with similar AMS vector orientations. This boundary corresponds to Dereköy-Hirfanlı Fault Zone.
6. During the late Cretaceous Tuz Gölü and Kırıkkale-Bala basins was subjected to NE-SW extension and NW-SE contraction while Hayman Basin was subjected to NS-contraction and E-W extension. In the same time Alcı-Orhaniye Basin was subjected to NW-SE extension and NE-SW contraction.
7. Palaeocene time interval is characterized by NW-SE extension and NE-SW contraction. This is possibly due to regional NE-SW extension in the region.

8. Eocene-Oligocene time interval is characterized by NW-SE contraction in the north of Dereköy-Hirfanlı Fault zone during which N-S contraction in the Haymana Basin and NE-SW contraction in the Tuz Gölü Basin dominated.
9. During the Miocene and Pliocene time intervals Dereköy-Hirfanlı Fault Zone was possibly inactive and there is not much change in the contraction and extension direction in the study area except the western part of Hayman Basin where the contraction and extension directions swapped.
10. AMS results proved that they are useful in understanding the deformation styles in an area.

Figure 2.18. Generalized AMS results in the study area. Note that the Dereköy-Hirfanlı Fault Zone controls the deformation in the north and was active possibly during Late Cretaceous to Oligocene and it does not have any control over the Miocene and Pliocene units. Blue lines are approximate boundaries of the basins.

CHAPTER 3

LATE CRETACEOUS TO PLIOCENE VERTICAL AXIS BLOCK ROTATIONS IN NORTH CENTRAL ANATOLIA, TURKEY

3.1. Introduction

This chapter deals with the vertical axes rotations in the study area for the time period from Late Cretaceous to Pliocene. Here, the results of paleomagnetic measurements and their analysis will be presented based on their age. For this purpose, the results are classified into five time periods namely, Late Cretaceous, Paleocene, Eocene-Oligocene, Miocene, and Pliocene epochs. In addition, the results are grouped into clusters based on their spatial distribution and consistency. These spatial domains include Haymana, Alcı-Orhaniye, Kırıkkale-Bala, and Tuz Gölü basins (Figure 3.1). This does not exclude the possibility that these domains were integral parts of now disconnected a large basin complex. However, such a discussion is out of scope of this thesis.

3.2. Paleomagnetic Sampling

Total numbers of 4630 oriented cylindrical samples from 119 sites have been collected in the study area. Out of these samples, only 751 samples from 16 sites belongs to Upper Cretaceous rocks, 1354 samples from 33 sites belongs to Paleocene rocks, 1603 samples from 31 sites belongs to Eocene to Oligocene rocks, the Miocene epoch was represented by 615 samples from 26 sites, and the youngest, Pliocene, rock units are represented by 308 samples from 13 sites. In all of the 119 sites, minimum number of samples per site is 13 while maximum number of samples per site is 64. In addition to these, 648 oriented rock samples were also collected from a single site in a stratigraphic order. Almost all of the samples were collected from sedimentary rocks except for 4 sites where sampling was performed on volcanoclastic rocks (Figure 3.2 and 3.3; Table 3.1).

One site from late Cretaceous granitoids, in the Kırşehir Block, is also collected to check the coherence between cover and basement of the Tuz Gölü Basin. Usually, we obtained multiple specimens from a single core (i.e. long samples cut into 2 or 3 pieces as subsamples) which provided a chance to apply both thermal and alternating field demagnetization procedures as well as rock magnetic measurements on the same sample. It also provided means to compare single core results (AF/TH) for natural remnant magnetization directions (c.f. Gong *et al.*, 2008).

Samples were collected using handheld water cooled diamond coated drill bits, gasoline powered motor drill or with a water cooled-generator powered electric drill, depending of the rock type. Sample orientations and attitude of the bedding were measured with a magnetic compass which were corrected for present declination amounts, which is around 4.5° E for the study sampling period between 2012-14.

3.3. Paleomagnetic Measurements

3.3.1. Rock Magnetic Properties

The paleomagnetic samples were measured to determine their thermomagnetic behaviors under the different temperatures following the procedure describe in Huang *et al.*, (2013). The measurements were run in air, using a modified horizontal translation type curie balance, with a sensitivity of $\sim 5 \times 10^{-9}$ Am² (Mullender *et al.*, 1993) (Appendix A and B). Approximately 30-90 mg powdered samples were put into a quartz-glass sample holder and were held in place by quartz wool. Temperatures were increased in a number of heating and cooling cycles up to a maximum of 700°C. Heating and cooling rates were 10°C /min.

Figure 3.2. a) Simplified geological map of the study area showing the location of the paleomagnetic sites. The red dashed rectangle shows enlarged version of Haymana Basin (simplified from Ünalın *et al.*, 1976, 1/500.000 scale maps of MTA 2002).

Figure 3.3 Blow up view of the Haymana Basin displaying the sample locations and local geology (simplified from Ünalın *et al.*, 1976, 1/500.000 scale maps of MTA 2002) (see Figure 3.2. for its location).

Table 3.1. Results of all measurements for vertical axis rotations.

*: Volcanic samples, Nc: number of collected sample for each site, Nm: number of demagnetized specimens, NvD: number of specimens included in the calculation for the mean ChRM direction after applying Vandamme cut-off, Dec/I: declination / inclination, ΔD_x / (ΔI_x): errors in declination / (inclination) determined from the A95 of the poles, k: estimate of the precision parameter determined from the ChRM directions, a95: cone of confidence determined from the mean ChRM directions for in situ and tilt corrected data, K: precision parameter determined from the mean virtual geomagnetic pole directions (VGPs), λ : paleolatitude, A95: cone of confidence determined from the mean VGP direction, $A95_{\min} / (A95_{\max})$: minimum / (maximum) value of the A95 for the given dataset based on (Deneen *et al.* 2011, 2014).

Figure 3.4 illustrates 18 representative examples of thermomagnetic experiment results for Upper Cretaceous to Paleocene rock units in the central Anatolia (Appendix A). Thermomagnetic analysis of 18 sites underwent alteration of iron sulphite, transforming above $\sim 400^{\circ}\text{C}$ to a more magnetic phases from pyrrhotite to magnetite around 580°C and finally above $580\text{-}650^{\circ}\text{C}$, to hematite (Figure 3.4).

The results show that the samples have various magnetic carriers in each site and a few sites have weak or scarcely distributed magnetic minerals in it (Appendix A). As seen in the thermomagnetic diagrams, we computed total magnetization in a series of runs to increasingly higher temperatures (up to 700°C). Individual data points have been omitted for clarity. Cycling field varied between 150 and 300 mT. In general, pale color marl, silt and limestone samples show very weak magnetization (saturation of remanence) (sites; R10, R20, R34, RN10). The majority of the samples have a reasonable amount of magnetic mineral compositions in them. For example; some samples show a reversible behavior during the heating-cooling cycle (decrease in magnetization with increasing temperature up to $\sim 410^{\circ}\text{C}$) that is typical greigite dominant matrix (sites; R38, R53, R55, R60, R65, RH1 and RH2) (Figure 3.4 and Appendix A).

Some samples have reversible smooth decrease in a magnetization between $100\text{--}400^{\circ}\text{C}$ continue with a sharp decline in intensity between $400\text{--}600^{\circ}\text{C}$, which is characteristic for low Ti-Magnetite (sites; R11, R22, R41, R73, SEC2) (Figure 3.4 and Appendix 3.1). Hematite dominant matrix shows smooth decline in the intensity between $20\text{--}580^{\circ}\text{C}$ and meaning fully large enough for paleomagnetic interpretations (sites; R12, R62, R64, R77, R83, SEC3) (Figure 3.4 and Appendix A).

In some sites reversible curves have low intensity values but decreasing up to 650°C indicate that the hematite mineral is the magnetic carrier (sites; R56, R59, R68, RN2, RN3, RN11) which is characteristic with their red color in the field (Figure 3.4 and Appendix A). The heating curves of some sites show an abrupt decrease in intensity between $20\text{--}100^{\circ}\text{C}$ which can be due to the existence of the goethite, an iron oxyhydroxide mineral.

Most of the sites, apart from some pale color marls and limestone samples, have suitable magnetic bearing mineral composition such as magnetite, ti-magnetite, hematite, pyrrhotite, greigite, etc. (Figure 3.4). Characteristic maximum blocking temperature for the magnetite $\sim 580^{\circ}\text{C}$ or maximum blocking under the magnetic field of 60-100 mT were selected to determine the ChRM direction. For few sites, demagnetization steps go up to 680°C , indicating typical maximum blocking temperature for hematite bearing samples. Some samples show low blocking temperatures around $340 - 475^{\circ}\text{C}$ and magnetic field between 25-45 mT. This implies that the remanence is mainly carried by greigite (Roberts, 1995; Vasiliev *et al.*, 2008; Rowan *et al.*, 2009).

18 thermomagnetic results belong to the youngest rocks that span between Eocene to Pliocene (Figure 3.5). Here, at least one thermomagnetic measurements were performed for each site and the results are given in Appendix B.

At the NE part of the study area, in the Kırıkkale-Bala Basin; we measured high initial magnetization intensities (total magnetization, $2- 3 \times 10^{-5} \text{ Am}^2 / \text{mg}$) from the Eocene sedimentary rocks (R17, R66, and R70) (Figure 3.5). Representative specimens show an irreversible decrease in magnetization around $530-580^{\circ}\text{C}$, implying the existence of magnetite as magnetic carrier in the sites R66 and R70. At site R17, initial intensity is low ($1.2 \times 10^{-6} \text{ Am}^2 / \text{mg}$) compared to the other two sites but the show irreversible decreases again around 580°C indicating that magnetite as magnetic carrier for Miocene deposits in the site.

The Tuz Gölü Basin is represented by three thermomagnetic samples from the sites R18 (Miocene), R84 and R86 (both are Eocene) (Figure 3.5). The Eocene sites have high initially intensities ($3-20 \times 10^{-6} \text{ Am}^2 / \text{mg}$) while Miocene site (R18) shows low initially intensity ($5 \times 10^{-7} \text{ Am}^2 / \text{mg}$) similar to results from the Miocene samples in the Kırıkkale- Bala Basin.

Two thermomagnetic experiments from Miocene volcanic and sedimentary units and one andesitic rock from the Eocene in the northwestern part of the study area, in the Alcı-Orhaniye Basin, indicate that the Eocene site (sample S7.13C) shows a progressive quasireversible decrease up to $\sim 640^{\circ}\text{C}$, followed by a more rapid

decrease up to 700°C so the dominate magnetic carrier is hematite. The last two Miocene sites (R13 and R31); one is volcanic (R13) indicate high initial intensity up to $3 \times 10^{-5} \text{ Am}^2 / \text{mg}$ and irreversible decrease around 580°C indicate magnetite composition. However, the other Miocene sedimentary sample (R31) shows Ti-rich magnetite from its heating curves and decreases around 400°C (Figure 3.5). In the Haymana Basin, between Polatlı and Haymana, three results one from Miocene and two from Eocene show magnetite, pyrrhotite, and Ti-rich magnetite dominance from the sites R24, R57 and SEC1, respectively. Southernmost part of the study area is represented by three sites (two Eocene and one Miocene site). The Thermomagnetic results indicate Ti-rich, pyrrhotite mineral from the Eocene rocks (R 33 and R 58, respectively) and hematite from the Miocene rocks (SF6).

Total number of 36 thermomagnetic results from Upper Cretaceous to Pliocene rocks (Figure 3.4 and 3.5) clearly indicate that the rest of 83 sites have coherent results which have high isolation ranges (both thermal and alternating field) to determine ChRM direction from 119 sites (Appendix B).

3.3.2. Demagnetization Procedure (AF/TH)

Characteristic remnant magnetization (ChRM) directions were isolated by applying both thermal (TH) and alternating field (AF) repeatedly stepwise demagnetization processes. For each sites, minimum number of seven specimens were fully cleaned thermally from secondary magnetic field effects and half of the samples in each sites were measured in AF that first heated and measured up to 150°C thermally before the full AF demagnetization process was applied in order to isolate possible stress in magnetite grains due to oxidation at low temperatures (Van Velzen and Zijdeveld, 1995; Gong *et al.*, 2008). TH demagnetization process was performed in a magnetically shielded oven (ASC, model TD48-SC) that has a residual field < 10 nT. Each specimen progressively demagnetized and measured by successive temperature steps at from 20°C, 80°C, 120°C, 150°C, 180°C, 200°C, 225°C, 250°C, 275°C, 300°C, 320°C, 340°C, 380°C, 420°C, 450°C, 450°C, 500°C, 530°C, 560°C, 580°C up to complete demagnetization of the naturel remnant magnetizations (for some samples if the magnetic carrier is hematite, the stepwise heating and measurement performed up to 700°C).

Figure 3.4. Thermomagnetic results measured on a Curie balance (Mullender et al, 1993) for representative of the upper Cretaceous to Paleocene rocks.

Figure 3.5. Thermomagnetic results measured on a Curie balance (Mullender et al, 1993) for representative of the Eocene to Miocene rocks.

The NRM of the specimens were measured on a 2G Enterprises horizontal 2G DC SQUID cryogenic magnetometer (noise level $3 \times 10^{-12} \text{ Am}^2$) hosted in the Fort Hoofddijk Paleomagnetic Laboratory, Utrecht University (the Netherlands). The AF demagnetization was carried out with increments of 3–10 mT, up to a maximum of 100 mT. The AF demagnetization and measurement process was carried out with an in-house developed robotized sample handler attached to a horizontal pass-through 2G Enterprises DC SQUID cryogenic magnetometer (noise level $1\text{--}2 \times 10^{-12} \text{ Am}^2$) hosted in the magnetically shielded room. Representative results of demagnetization steps of AF and TH are illustrated on the orthogonal vector diagrams. In order to compare AF and TH results in each site, we illustrated both thermal and alternating field demagnetization results in the same figure (Figures 3.6). Detailed information about the results per site is given in Table 3.1 and further details can be found in the Appendices 3.1 and 3.2.

3.3.3. Analysis of ChRM directions

In order to illustrate all the demagnetization results (steps) of the NRM, we used orthogonal vector diagrams (Zijderveld, 1967) (Figure 3.6), as well as the equal area projections of the ChRM (Figure 3.7). In orthogonal diagrams, the ChRM directions were determined using principal component analysis (Kirschvink, 1980) by taking approximately five to seven or more successive points from TH or AF demagnetization steps. Few samples, overprinted at least two overlapping coercivity or temperature components, were analyzed using the great circle approach (McFadden and McElhinny, 1988) (Figure 3.6). With the help of this method, the ChRM directions that lie around a great circle, the average direction from well-defined NRM directions can be determined. Since the results of ChRM distributions effected by the certain amount of secular variation of the Earth's magnetic field after the initial remanence were obtained which is circular at the poles, but gradually becomes more ellipsoid towards the equator (Creer *et al.*, 1959; Tauxe and Kent, 2004, Deenen *et al.*, 2011). Therefore, we calculated from the ChRM directions of each samples, site means (K) as well as virtual geomagnetic poles (VGP) and their means (A95, the 95% cone of confidence of the VGPs) were computed using Fisher statistics (Fisher 1953). A fixed cut-off (45°) was

Figure 3.6. Results of orthogonal vector diagrams (Zijderveld, 1967), illustrating representative characteristic demagnetization diagrams for each site comprising the late Cretaceous to Paleocene time interval. Closed (open) circles indicate the projection on the horizontal (vertical) plane. All diagrams converted to their initial bedding (horizontal) positions. Both thermal (steps in °C) and alternating field (milliTesla, mT) demagnetization diagrams are shown for two specimens from the same site for comparison. Note that the site R53 did not produced any TH results.

(Figure 3.6 continued)

(Figure 3.6 continued)

(Figure 3.6 continued)

applied to remove outliers as explained by Deenen *et al.*, (2011, 2014). The VGPs per site and the corresponding errors in declination (ΔD_x) and error in inclination (ΔI_x) determined individually according to Butler (1992). Deenen *et al.*, (2011, 2014) proposed N-dependent reliability criteria for dataset which assess whether the statistical results may be verified by the secular variations alone or not. On the contrary most of the paleomagnetic studies used the criteria proposed by Van der Voo (1990) but the criteria suggested by Deenen *et al.* (2011) are individually applied for each data set, in this study. In order to identify whether two distributions have a common true mean direction (CTMD), we used the reversal test proposed by McFadden and McElhinny (1990) and their classifications (A, B, C, indeterminate) in terms of the critical angle γ_c and the angle γ between the means. Since we operate their test with simulation, which is equivalent to Watson (1983)'s V_w statistical parameter.

3.3.4. Data Reliability

In order to verify the reliability of the obtained results following reliability criteria have been applied. Other than six sites which belong to Miocene volcanoclastic rocks in the Haymana Basin and one Permian limestone block from the Karakaya Complex and one site from the late Cretaceous granite (basement of Tuz Gölü Basin), in all other site sedimentary rock units are sampled. It is already known that the secular variation effects are minimal to negligible in the sedimentary rocks due to a fact that 1.3cm thick fine clastic sediment may represent few hundred to thousand year therefore the secular variation is smoothed out. In addition, sedimentary rocks provide good constraints on the position of the paleohorizontal (original horizontality of bedding plane). Therefore, sedimentary rocks are more reliable in terms of secular variations and finding paleohorizontal which is collectively known as tectonic or tilt correction. However, volcanic rocks are prone to secular variation since they are spot readings owing to be cooled off within few hours to days. Paleohorizontal is generally difficult to determine for both volcanic and plutonic rocks are on fine minimized and also the initial bedding positions (accepted horizontal) are more reliable than the intrusive bodies. According to Jackson *et al.* (2000) the paleosecular variations (PSV), might reach up to $\pm 25^\circ$ or more depending on the latitude (higher latitudes has higher angular variation).

Figure 3.7. Equal area projections of the ChRM directions of all sites from late Cretaceous to Pliocene. Open (solid) symbols denote projection on upper (lower) hemisphere. Large symbols indicate respectively the mean directions and their cone of confidence (a95). Red (small) circles indicate the individual directions rejected by the Vandamme cut-off angle (45°) (Vandamme, 1994). Note that only one site (S2 did not produce any results).

(Figure 3.7 continued)

(Figure 3.7 continued)

(Figure 3.7 continued)

(Figure 3.7 continued)

Although, majority of our samples are collected from sedimentary rocks which have lower chance of paleosecular variations, nevertheless, we followed the criteria proposed by Deneen *et al.* (2011, 2014) in order to overcome this problem. According to these criteria a cone of confidence is determined based on the maximum and minimum values within the $A95_{max}$ and $A95_{min}$ of VGP cone of the site. Any sample with results out of this cone implies that these datasets are influenced by the PSV effect or samples comprise a short time span (spot sampling). If $A95$ larger than the $A95_{max}$, the results are not only effected by the secular variations but might as well be affected by the combination of vertical axis rotation and tilt differences within the dataset.

In order to reduce the effect of PSV on results, each sample was collected from different stratigraphical levels and in the sections few meters apart. In order to cover larger thickness and time interval. In some sites, both normal and reverse polarities were measured within the same section, therefore, we applied reversal test to verify the reliability of the data.

However, some of the sites (R43, R60, R75 and R83) (Table 3.1) erratic NRM directions (e.g. N/up, S/down) are detected which do not fit the general mean rotations possibly due to close proximity to a major fault zone or they are struck by lightning. Such sites are refrained from further analysis.

3.4. Paleomagnetic Rotations

Paleomagnetic rotations are evaluated based on their age and location. Spatially the results show very distinct pattern in different part of the study area. For this reason the study area subdivided into sub areas based on the sampled lithologies and tectonic history of the study area. The sub areas include counter-clockwise from SE to NE to NW to SW include Tuz Gölü, Kırıkkale-Bala, Alcı-Orhaniye and Haymana basins (Figure 3.7)

3.4.1. Late Cretaceous & Older Rocks

Upper Cretaceous and older rocks are represented by 16 sites (Figure 3.9a and b, Table 3.1). Among these 16 sites, two of them were rejected because the initial magnetic remanence has been partly overprinted by present day magnetic field in site

R67 and the site R83 produced uninterpretable and unrealistic results (Figure 3.8). The overall rotation results in these rocks indicate a very large swath of rotations as large as $\pm 80^\circ$ in both clockwise and counter-clockwise senses.

The oldest site belongs to the Permian Limestone blocks of Karakaya Complex (R10). The results from this site shows normal polarity with $D=28.5^\circ$, $I= 49.5^\circ$ sense. This indicates an approximately 28° clockwise rotation and very high inclination value that is little bit south of present day latitude of the block. Therefore, it must be remagnetized possibly during Eocene or younger periods.

Two Upper Cretaceous sites in the Kırıkkale-Bala Basin show clockwise rotations. The site R 65 has both normal and reverse magnetic polarity and yielded $D=74^\circ$, $I= 46.2^\circ$ indicating 74° clockwise rotation. The site R 73 has reverse polarity and the yielded $D=242.3^\circ$, $I= -41.9^\circ$ which indicate as high as 80° clockwise rotations.

There is only one Upper Cretaceous site (RN 6) in the Alcı-Orhaniye Basin and yielded reverse polarity of $D=184.2^\circ$, $I=-34.4^\circ$ which indicates almost no rotation.

In the Haymana Basin all of the 9 Upper Cretaceous sites yielded counter-clockwise rotations. 7 of the total 9 sites, show strong counter-clockwise rotations with declination values varying between $D=281.7^\circ$ - 301.3° and they have both normal and reverse polarities. On the other hand, the declinations seem to decrease in the western part of the Haymana basin around Polatlı. The remaining two sites (R 21 and R 55) in this part of the basin has relatively lower counter-clockwise rotations compared to the eastern sites. R 21 has $D=309.4^\circ$, $I= 55.9^\circ$ from 28 measurements and R 55 has $D=321.3^\circ$, $I= 50.0^\circ$ from 26 measurements.

3.4.2. Paleocene vertical axis rotation

Paleocene paleomagnetic data in the study area is represented by 33 sites (Table 3.1, Figures 3.10 and 3.11). They have both clockwise and counter-clockwise senses. The detailed information about the results per sub area is given below.

Apart from one site (R 60) which produced reverse polarity and counter-clockwise rotation ($D=122.3^\circ$, $I= -46.3^\circ$) all other 5 Paleocene sites in the Kırıkkale-Bala Basin show consistent clockwise rotations that vary between $D=4.3^\circ$ to 71.5° and have both

normal and reverse polarities. At the southern part of the Kırıkkale-Bala Basin near Bala, the site R 75 produced normal polarity and very large counter-clockwise rotations as high as 128° and the obtained declination and inclination values are as follows $D=232.6^\circ$, $I= 53.1^\circ$. Rest of two the sites (R 74 and R 76) shows consistently counter-clockwise rotations with ChRM result; $D=324.3^\circ$, $I= 37.3^\circ$ for the site R 74 and $D=353.5^\circ$, $I= 37.3^\circ$ for the site R 76. On the other hand, from the site R 77 which is located at the south-easternmost part of the study area and in the Tuz Gölü Basin and produced clockwise rotations with ChRM results; $D=77.2^\circ$, $I= 46.3^\circ$. In this site 7 of the samples were reversely polarized while the remaining 11 of them were normally polarized.

Figure 3.8. Upper Cretaceous and Older age 16 sites vertical axis rotation vectors with their error envelop illustrated in grey.

Figure 3.9. a) Late Cretaceous and Older paleomagnetic rotation vectors plotted on the general geological and structural settings in the study area. **b)** Blow up view of the Haymana Basin displaying the results of the Late Cretaceous sites paleomagnetic rotation vectors. Note that R10 belongs to Karakaya complex (pre-Cretaceous) and OA belongs to late Cretaceous granitoids of Kırşehir Block.

From the northwestern part of the study area, in the Alci-Orhaniye Basin, we have only two Paleocene sites (R 1 and R 2) which are consistently produced clockwise rotations with ChRM (N=30) result; $D= 82^{\circ}$, $I= 52^{\circ}$ in the site R1. In this site 12 specimens were reversely polarized while the remaining 18 of them were normally polarized. The site R2 has ChRM (N=25) results; $D=35.4^{\circ}$, $I= 58.9^{\circ}$.

At the western part of the area between Temelli and Polatlı, there are 5 Paleocene sites (R 11, R 12, R 20, R 22, and SEC 2). All of these sites show counter-clockwise rotations that vary between $D=292.7^{\circ}$ - 314.1° . Two sites (R 20 and R 22) have reverse polarity. One site (R 43) has very large declination and inclination values ($D: 205^{\circ}$, $I: 80^{\circ}$).

In the Haymana Basin two distinct and opposite rotation senses are observed. Near Haymana town center, from 7 sites (R 25, R 56, RN 3, RN 11, R 34, K-T, R 39) counter-clockwise rotations with declination values varying between 236.6° - 334.6° have been obtained (Table 3.1, Figures 3.10 and 3.11b). Towards the southwestern part of the basin the paleomagnetic direction results show opposite senses of (clockwise) rotations in the seven sites (R53, RN2, RN9, R36, R59, R48). The clockwise rotation results change between 23° to 72.1° .

3.4.3. Eocene to Oligocene Rotations

Eocene-Oligocene period is represented by 31 sites. Among these, two sites (R 23 and RN 1) did not pass the Vandamme cut-off (45°) and they are not included in any further analysis (Table 3.1). The rest of 29 sites scattered in the area produces reliably results that show interpretable rotation pattern (Figures 3.12 and 3.13).

From the northeastern part of the study area, in the Kırıkkale-Bala Basin, four Oligocene sites (R63, R66, R70, and R72) produced clockwise rotations. The rotation directions vary between 22.5° up to 100° clockwise sense. In addition, two of these sites have normal polarization while the other two sites were reversely polarized.

The Tuz Gölü Basin is represented only by two Eocene sites they show counter-clockwise rotations (R85: $N=21$, $D=163.8^{\circ}$, $I= -49.6^{\circ}$ and R 86: $N=11$, $D=304.2^{\circ}$, $I= 67.6^{\circ}$). They are all normally polarized and are opposite to the results of the Kırıkkale-Bala Basin which are located at the north and have clockwise rotations.

Figure 3.10. Declination values and corresponding error parachutes of 33 Paleocene sites in the study area.

Figure 3.11. a) Paleocene rotation vectors plotted on the general geological and structural settings in the study area. b) Blow up view of the Haymana Basin displaying the results of the Paleocene sites paleomagnetic rotation vectors.

In the Alcı-Orhaniye Basin, which is located at the NW part of the study area, three sites yielded clockwise rotations ranging between 18° - 60° (S8: N=10, D= 198.4° , I= -37.2° ; S9: N=17, D= 60.8° , I= 55.5°).

Haymana Basin is represented by 24 sites (Table 3.1, Figure 3.13). Two of the sites (RN 1 and R 23) did not yield any appreciable results so they are not used for further analysis. The rest of 22 sites show both clockwise and counter clockwise rotations. Especially near Haymana town center, four sites (R 26, R 40, R 42, R 57) show counter-clockwise rotations, while further south of the town 12 sites (R 33, R 54, R 42, R47, SEC 5, RN 4, R 81, R 79, R 80, R 52, R 49, RN 5) yielded clockwise rotations. However, two sites (R 58 and R 82) within the clockwise domain yielded counter-clockwise rotations contrary to the nearby clockwise sites.

3.4.4. Miocene Rotations

From 26 Miocene sites 615 samples were collected (Table 3.1). Among these 5 sites did not produce any reliable results therefore they are not used in any further analysis. The remaining of 21 sites produced meaningful results. Among them three sites belong to volcanic rocks while the rest of them are collected from sedimentary rocks. The results are depicted in Figures 3.14 and 3.15.

The results are evaluated on the basis of sub areas (basins). In the Kırıkkale-Bala Basin the site R 71 show slightly clockwise rotation (8.0 ± 17.8 , N=14). Between the Kırıkkale-Bala and the Haymana basins, the rotation vectors show generally clockwise senses except for two sites (R8 and RN18) which yielded counter-clockwise rotations. The other five sites (two of them are volcanic) in the region shows clockwise rotation that vary between 6° to 55° (R46: N=21, D= 6° , I= 51° , R 17: N=17, D= 55.5° , I= 63.2°). The site R46 has 5 while R17 has 14 reverse polarity samples. The site R 78 did not produce any reliable results from 15 measured specimens.

Figure 3.12. Declination values of Eocene sites with their error envelop (grey parachutes).

Figure 3.13. a) Eocene to Oligocene rotation vectors plotted on geological map. **b)** Blow up view of the Haymana Basin displaying the results of Eocene rotation vectors.

Figure 3.14. Miocene age 21 site rotation vectors with their error envelopes illustrated in grey.

Figure 3.15. a) Miocene rotation vectors plotted on the general geological and structural settings in the study area. **b)** Blow up view of the Haymana Basin displaying the results of the Miocene sites paleomagnetic rotation vectors.

In the Alci-Orhaniye Basin, out of five sites one site (S2) did not produce any reliable result, all of the other four sites (S 1, S 3, R 13, RN 7) show counter-clockwise rotations ranging between 2° to 27° (S3: , N=19, D=358.3°, I= 75° and S1: N=46, D=332.6°, I= 45°). All the specimens show normal polarity. In addition, in the southernmost part of the Alci-Orhaniye Basin, a cluster of five sites (S5, S6, R29, R30, and R31) show counter-clockwise rotations with mean direction of $\sim 340 \pm 7^\circ$.

The Miocene in Haymana Basin is represented by three sites (Figure 3.15). Among these, one site (R4) shows counter-clockwise rotation (N=29, D=319.7°, I= 52.9°) whereas the other two sites (SF6 and SF2) indicate clockwise directions up to 27° (N=20, D=2.5°, I=54.6°; and N=16, D=27.4°, I= 48.9°, respectively).

3.4.5. Pliocene Rotations

The Pliocene paleomagnetic data comprises, totally 13 sites (Figure 3.16 and 3.17, Table 3.1). There is no paleomagnetic site in the Kirikkale-Bala Basin. Both Tuz Gölü and Alci-Orhaniye basins are represented by only one site each. The site in the Tuz Gölü basin (R84) yielded from 21 specimens D=163.8°, I= -49.6° results. All of the specimens are reversely polarized. On the other hand, only one specimen was reversely polarized while the remaining ones were normally polarized in the single site in the Alci-Orhaniye Basin (R28) and yielded from 15 specimens D=345.2°, I= 46.4°.

The remaining 11 Pliocene sites belong to Haymana Basin. Between Polatlı and Temelli town centers, in other words, in the northern part of the Haymana Basin, two sites yielded counter-clockwise rotations. In site R 25 out of 17 samples D=326.9°, I= 49.4° results are obtained. The other counter-clockwise site is R24 and out of 20 samples it yielded D=153.5°, I= -48.5° results. In this site all specimens were reversely polarized.

In the southern part of the Haymana Basin, all the samples indicate clockwise rotations except for the site R51 that has about 15° counter-clockwise rotation (D=165.1°, I= -38.7°) out of 20 samples. In this site, all the specimens are reversely polarized. The other 8 sites (R3, R5, R 32, R37, R 50, SF 4, SF 3, and SF 1) all have clockwise rotations ranging between 2° to 35°. In this part of the Haymana Basin,

one site (SF5) did not produce any interpretable signal and it is excluded from further analysis. All the results are given in the Table 3.1 and in Appendices.

Figure 3.16. Declinations and corresponding error parachutes (grey wedges) of Pliocene sites in the study area.

3.5. Discussions

3.5.1. Evaluation of Paleomagnetic Results

The paleomagnetic results have indicated that the rotation patterns within each basin is relatively consistent (Figure 3.18, Table 3.2). Among these, the results of Tuz Gölü, Kırıkkale-Bala and Alcı-Orhaniye Basin are internally consistent whereas Haymana Basin has controversial results (Figure 3.18).

Figure 3.17. a) Mean Pliocene declinations plotted on the geological map. Dash-line box is the location of (b) blow up view of Haymana Basin.

The calculated mean statistics for basins from per locality in each basin are consistent which implies that they can be considered as independent blocks except for Kırıkkale-Bala and Alcı-Orhaniye basins which seems to belong to same block although they are separated by a major metamorphic belt (Figure 3.18.). Nevertheless, for the sake of consistency, each basin will be dealt with separately in the forthcoming section. In order to calculate mean block rotation amounts all the sedimentary data for different time intervals are grouped and analyzed together for each block. In other words, all the sedimentary specimens from each site in each basin are evaluated collectively for each block.

The magmatic rocks due to their intrinsic magnetic properties they are not included in this analysis. During the analysis of the results all the declinations are normalized with respect to north (normal) for statistical reasons (see Appendices and Supplementary).

In the next sections the declination results for each basin and each time interval is discussed.

3.5.1.1. The Kırıkkale-Bala Basin

The mean declinations of 49 Miocene samples from three sites indicate that the Kırıkkale-Bala Basin rotated $34.4 \pm 7.3^\circ$ clockwise. The basin does not have any Pliocene and younger sites.

The Eocene to Oligocene is represented by four sites and they indicate very coherent directions ($a_{95}=4.3$) (Figure 3.19). The results of the four sites show quite large amounts of clockwise rotations which is $73.7 \pm 8.9^\circ$ (Figure 3.19, Table 3.2).

The Paleogene Kırıkkale-Bala Basin is represented by three Upper Cretaceous, six Paleocene, four Eocene and Oligocene, and three Miocene sites (Figures 3.19 and 3.20, Table 3.2).

Nm: number of demagnetized specimens/mean ChRM direction per site under AF/TH, NvD: number of specimens/mean direction included in the calculation for the mean ChRM direction after applying the 45° fixed cut-off, Dec/I: declination/inclination, ΔD_x / (ΔI_x): errors in declination / (inclination) determined from the A95 of the poles, k: estimate of the precision parameter determined from the ChRM directions, a95: cone of confidence determined from the mean ChRM directions for in situ and tilt corrected data, K: precision parameter determined from the mean virtual geomagnetic pole directions (VGPs), λ : paleolatitude, A95: cone of confidence determined from the mean VGP direction, A95min / (A95max) : minimum / (maximum) value of the A95 for the given dataset based on (Deneen *et al.*, 2011, 2014).

Figure 3.18. Mean declination vectors per site for different time intervals. The boxes indicate the data clustered for each basin to determine mean block rotation vectors.

Paleocene of Kırıkkale-Bala basin is represented by 84 samples from five sites. The average declination vector indicates large clockwise rotation amount of $45.7 \pm 5.1^\circ$ from the Kırıkkale-Bala Basin (Figure 3.19, Table 3.2). All the specimens have normal polarity (Figure 3.20).

The oldest studied time interval in Kırıkkale-Bala Basin is late Cretaceous and represented by 32 samples from two sites. The mean vector indicates very large clockwise rotations which is $70.3 \pm 6.9^\circ$ (Figure 3.19, Table 3.2).

3.5.1.2. The Tuz Gölü Basin

Only one Pliocene site (R 84) represents the Tuz Gölü Basin. The results of the site indicates 16° counter-clockwise rotation with $N=21$, $D: 163.8 \pm 3.1^\circ$, $I: -49.6$ results (Figures 3.21 and 3.22, Table 3.2).

Similarly, the Miocene is also represented by one site (R 18) with 20 samples. The results show that the site mean rotation amount is 15° counter-clockwise (D: $344.5 \pm 9.0^\circ$ and I: 43.4) (Figure 3.21 and 3.22, Table 3.2).

Eocene - Oligocene interval in the Tuz Gölü Basin is represented by two sites (Table 3.2). The results of combination of these two sites out of 32 samples, produced consistent result with 40° counter-clockwise rotations (D: $319.6 \pm 8.9^\circ$, I: 64.8°). All the samples have normal polarity.

Figure 3.19. Paleomagnetic vector diagrams of Upper Cretaceous to Pliocene rocks in the Kırıkale-Bala Basin. Equal area projections of the ChRM directions determined from specimens in five time intervals. Open (solid) symbols denote projection on upper (lower) hemisphere. Large symbols indicate respectively the mean directions and their cone of confidence (a95). Red (small) circles indicate the individual directions rejected by the cut-off angle 45° (Vandamme, 1994).

Figure 3.20. Equal area, lower hemisphere projection of all the samples in Kırıkkale-Bala Basin for different times intervals. Large blue circles are mean directions and their error range, black dots are (normal polarity) and small circles (reverse polarity) individual samples and red dots are rejected samples after 45° (Vandamme 1994) filter is applied.

Figure 3.21. Paleomagnetic vector diagrams of Upper Cretaceous to Pliocene rocks in the Tuz Gölü Basin. Equal area projections of the ChRM directions determined from specimens in five time intervals. Open (solid) symbols denote projection on upper (lower) hemisphere. Large symbols indicate respectively the mean directions and their cone of confidence (a95). Red (small) circles indicate the individual directions rejected by the cut-off angle 45° (Vandamme, 1994).

Figure 3.22. Equal area, lower hemisphere projection of all the samples in the Tuz Gölü Basin for different times intervals. Large blue circles are mean directions and their error range, black dots are (normal polarity) and small circles (reverse polarity) individual samples and red dots are rejected samples after 45° (Vandamme 1994) filter is applied.

Similarly, the average Paleocene rotation results are obtained from two sites (R 74 and R 76) in the Tuz Gölü Basin (Figure 3.21, Table 3.2). The combination of these sites, out of 37 samples, indicate 18° counter clockwise rotations (D: $341.7 \pm 5.4^\circ$, I: 38.2°). Low inclination value is most probably due to flattening effect. The late Cretaceous is represented by only one site (OA) in the Tuz Gölü Basin. The other contemporaneous site (R83) did not produce interpretable results and rejected. The site OA belongs to granitoids in the basement of the Tuzgölü Basin. The site mean rotation direction, out of 8 samples, indicate 29° counter-clockwise rotations (D: $151.5 \pm 8.9^\circ$, I: -58.4°) (Figure 3.22, Table 3.2).

3.5.1.3. The Alcı-Orhaniye Basin

The Alcı-Orhaniye basin is located at the NW part of the study area. It constitutes the integral part of the Haymana Basin and underlain by the Pontide Block. The paleomagnetic results are clustered for five time intervals ranging from the late Cretaceous to Pliocene. The youngest data set represents the Pliocene of the basin and comprises only one site (R28). From 15 samples D: $345.2 \pm 9.7^\circ$, I: 46.4° results are obtained. Based on this data the basin is said to be rotated 14° counter-clockwise during the Pliocene (Figure 3.23, Table 3.2). All specimens have normal polarity (Figure 3.24). Eight sites (R 13 belongs to volcanic rocks) represent the Miocene of the basin (Figure 3.23). The mean directions calculated from 136 samples indicate 37° counter-clockwise rotation during the Miocene (D: $322.9 \pm 8.9^\circ$, I: 46.5°). The results from the volcanic site show slightly clockwise rotation of $1.6 \pm 7.9^\circ$. The data contain both normal and reverse polarities and produced positive reversal test ($\gamma = 14.2^\circ < \gamma_c = 8.6^\circ$, classification B) (Figure 3.24). For the Eocene-Oligocene rotation results three sites with total 44 samples are available (Figures 3.23 and 24). The resultant mean rotation amount and sense is 34° clockwise (D: $33.9 \pm 7.2^\circ$, I: 40.1°). The sites both normal and revers polarities the applied reversal test is negative ($\gamma = 37.8^\circ < \gamma_c = 8.6^\circ$, out of classification) (Figure 3.24).

The Alcı-Orhaniye Basin has two Paleocene sites (R1 and R 2) both have normal polarity. Mean direction for the whole basin, based on 56 samples, indicate 70° clockwise rotation (D: $70.1 \pm 6.9^\circ$, I: 56.3°) (Table 3.2). The site R10 is sampled for the basement of Alcı-Orhaniye Basin and it yielded D: 094.0° , I: 67.7° , from 17 samples. Although, the age of the sampled site is Triassic, however very high inclination values indicate that this site is remagnetized, possible during Eocene-Oligocene interval considering its possible paleolatitudinal position. The late Cretaceous of Alcı-Orhaniye basin is represented by only one site (R6). The results of this site indicate more around 65° clockwise rotation (D: 244.8° , I: -53.5°) based on 20 samples.

Figure 3.23. Paleomagnetic vector diagrams of Upper Cretaceous to Pliocene age rocks in the Alci-Orhaniye Basin. Equal area projections of the ChRM directions determined from specimens in five time intervals. Open (solid) symbols denote projection on upper (lower) hemisphere. Large symbols indicate respectively the mean directions and their cone of confidence (a95). Red (small) circles indicate the individual directions rejected by the cut-off angle 45° (Vandamme, 1994).

Figure 3.24. Equal area, lower hemisphere projection of all the samples in the Alçı-Orhaniye Basin for different times intervals. Large blue circles are mean directions and their error range, black dots are (normal polarity) and small circles (reverse polarity) individual samples and red dots are rejected samples after 45° (Vandamme 1994) filter is applied.

3.5.1.4. The Haymana Basin

Due to very contrasting paleomagnetic results the Haymana Basin is subdivided into two parts. The northern and southern part of the basin is analyzed separately.

3.5.1.4.1. Northern Part of the Haymana Basin

The northern part of the Haymana Basin characterized by counter clockwise rotation for all time intervals.

The combined result of two Pliocene sites (R 24 and R 27) resulted approximately 30° counterclockwise rotation ((D: 330.5±5.2°, I: 49.0°) out of 37 samples (Table

3.2, Figure 3.25). The sub-basin has both normal and reverse polarity samples. Therefore, we applied reversal test which is positive ($\gamma = 4.4^\circ < \gamma_c = 7.2^\circ$, classification B) (Figure 3.26).

The Miocene of northern part of Haymana basin is represented by only one site with 20 samples. The results show approximately 10° of counter-clockwise rotation (D: $349.8 \pm 4.6^\circ$, I: 51.8°) (Figure 3.26, Table 3.2).

Four sites, with 92 samples, represent the Eocene-Oligocene of northern part of the Haymana Basin. Among these one site has reverse polarity samples while the other three sites yielded normal polarity (Table 3.2). The combined results indicate approximately 44° counter-clockwise rotations (D: $315.7 \pm 4.5^\circ$, I: 40.9°) (Table 3.2). Since there are both normal and reverse polarities, the applied reversal test is negative due to shallow and scattered results in the reversal components (I: -34.8° , $a95=4.9^\circ$) ($\gamma = 13.6^\circ > \gamma_c = 6.5^\circ$, out of classification) (Figure 3.26).

Paleocene is represented by 12 sites with 251 samples (Table 3.2, Figure 3.25). Almost half of the samples are reverse polarized. The combined results show large counter-clockwise rotations (D: $312.6 \pm 3.0^\circ$, I: 47.3°). The ChRM vector distribution show well clustered results ($a95=2.6^\circ$, $k=14.2$). According to the normal and reverse components, the reversal test shows again shallow inclination (-37.2°) in the reversal components so the test is negative ($\gamma = 20.3^\circ > \gamma_c = 3.7^\circ$, out of classification) (Figure 3.26).

The oldest rotation data in the region belongs Upper Cretaceous sites (Figure 3.25). Only one site show completely reverse polarity and the other two sites have both normal and reverse polarities. The paleomagnetic result out of 449 samples indicate very large counter-clockwise rotations (D: $298.0 \pm 2.6^\circ$, I: 55.5°) (Table 3.2). The ChRM vectors are well clustered ($a95=1.8^\circ$). The applied reversal test is negative ($\gamma = 23.2^\circ > \gamma_c = 3.7^\circ$, out of classification) (Figure 3.26). This is most probably due to declination differences ($D_{\text{normal}}=292.6^\circ$ and $D_{\text{reverse}}=148.9^\circ$) and shallower inclination in the reverse polarities (56.3° versus -48.5°) (Figure 3.26).

Figure 3.25. Paleomagnetic vector diagrams of Upper Cretaceous to Pliocene rocks in the northern part of Haymana Basin. Equal area projections of the ChRM directions determined from specimens in four intervals. Open (solid) symbols denote projection on upper (lower) hemisphere. Large symbols indicate respectively the mean directions and their cone of confidence (a95). Red (small) circles indicate the individual directions rejected by the cut-off angle 45° (Vandamme, 1994).

Figure 3.26. Equal area, lower hemisphere projection of all the samples in the northern part of the Haymana Basin for different times intervals. Large blue circles are mean directions and their error range, black dots are (normal polarity) and small circles (reverse polarity) individual samples and red dots are rejected samples after 45° (Vandamme 1994) filter is applied.

3.5.1.4.2. Southern Part of the Haymana Basin

The Pliocene of the southern part of the Haymana Basin is represented by 9 sites (Figure 3.27). The mean of the 9 sites with 449 samples indicate that the sub-basin underwent 17° clockwise rotation (D: $17.2 \pm 2.6^\circ$, I: 52.3) (Table 3.2). The basin has both normal and reverse polarities and the reversal test is positive ($\gamma = 4.1^\circ < \gamma_c = 5.2^\circ$, classification B) (Figure 3.28).

Figure 3.27. Paleomagnetic vector diagrams of Upper Cretaceous to Pliocene age rocks in the Haymana Basin (south). Equal area projections of the ChRM directions determined from specimens in five time intervals. Open (solid) symbols denote projection on upper (lower) hemisphere. Large symbols indicate respectively the mean directions and their cone of confidence (a_{95}). Red (small) circles indicate the individual directions rejected by the cut-off angle 45° (Vandamme, 1994).

Two Miocene sites with total of 30 samples represent the basin. Both of these sites has normal polarity and mean rotation amount is around 6° (D: $6.3 \pm 7.5^\circ$, I: 51.2°) clockwise. One of these sites is volcanic and reverse polarity the other one is sedimentary and with normal polarity. The mean rotation from volcanic rocks has more clockwise rotation ($12.8 \pm 3.7^\circ$) than the sedimentary ones. The applied reversal test is negative ($\gamma = 11.4^\circ > \gamma_c = 5.8^\circ$, out of classification) (Figure 3.28).

The Eocene-Oligocene of the southern part of the Haymana Basin is represented by 15 sites and 254 total samples. Although, some of the results are rejected due to inconsistencies in directions, the general distribution of the ChRM directions are well clustered ($a_{95}=2.4$). The mean rotation amount is clockwise sense and direction of (D: $34.3 \pm 3.0^\circ$ I: 46.8). According to the reverse and normal polarities, the reversal test is negative ($\gamma = 262^\circ > \gamma_c = 7.0^\circ$, out of classification) (Figure 3.29).

The oldest units sampled level in the southern part of the Haymana Basin is Paleocene (Figure 3.27). It is represented by six Paleocene sites (Figure 3.27) with 115 samples. The mean Paleocene rotation is around 38° clockwise (D: $38.3 \pm 4.7^\circ$, I: 46.2°). The distribution to total number of 115 samples show fair clustering ($a_{95}=3.7$). The reversal test gives positive result ($\gamma = 4.1^\circ < \gamma_c = 7.2^\circ$, classification B) (Figure 3.28).

In addition to two sub areas, the data from Haymana Basin is also evaluated for whole basin. In order to accomplish this all the data from northern southern part of the basin is combined and analyzed. The Pliocene of the basin is represented by 183 samples and they indicate approximately 10° clockwise rotation during the Pliocene with D: 10.5° , I: 52.7° (Figure 3.29).

The Miocene is represented by 41 samples and they yielded D: 356.7° , I: 53.9° which indicates very slight counter-clockwise rotation of the basin. Eocene-Oligocene time interval comprises 303 samples which produced D: 33.9° , I: 46.9° . Very large part of the data is rejected due to 45° cut-off (Vandamme 1994). This value indicates approximately 34° clockwise rotation of the basin during Eocene.

Paleocene time interval in the Haymana Basin is represented by 321 samples and the yielded D: 312.8° , I: 47.5° . It indicates approximately 39° counter-clockwise rotation

during the Paleocene. In the analysis very large part of the data is excluded due to 45° cut-off (Vandamme 1994). Therefore, the obtained ChRM values represent smoothed rotation value of the basin.

Figure 3.28. Equal area, lower hemisphere projection of all the samples in the southern part of the Haymana Basin for different times intervals. Large blue circles are mean directions and their error range, black dots are (normal polarity) and small circles (reverse polarity) individual samples and red dots are rejected samples after 45° (Vandamme 1994) filter is applied.

The late Cretaceous of the Haymana Basin is represented by 374 samples all of which passed the 45° cut-off indicating that the results are consistent which are; D: 292.6, I: 56.3 (Figure 3.29). These results indicate approximately 67° counterclockwise rotation of the basin at the end of Cretaceous.

Figure 3.29. Equal area, lower hemisphere projection of all the samples in the Haymana Basin (data includes both northern and southern parts of the basin) for different times intervals. Large blue circles are mean directions and their error range, black dots are (normal polarity) and small circles (reverse polarity) individual samples and red dots are rejected samples after 45° (Vandamme 1994) filter is applied.

3.5.2. Timing of the vertical axis block rotations

The systematic sampling in the field and detailed paleomagnetic analyses show that there are very significant variations in the vertical axis rotations in the study area since the Late Cretaceous to Pliocene. Based on the spatial consistency of the rotations the study area is subdivided into five sub-areas. Each sub areas are analyzed for their mean rotations (Table 3.2). In order to calculate incremental rotation amounts of each basin for successive time interval, the younger rotation amounts are subtracted from the previous ones (Table 3.3). This would give the paleodeclination values for that particular interval for each basin. As seen in the Table 3.3, the late Cretaceous units in Kırıkkale-Bala Basin had paleodeclination values of 024.6°N. It means that by the end of the Late Cretaceous the basin infill of Kırıkkale-Bala basin must have been rotated clockwise approximately 24°.

Likewise, during the Paleocene in the Kırkkale-Bala Basin 28° counter-clockwise rotation, in Tuzgölü Basin 6.4° clockwise rotation, in Alcı-Orhaniye Basin 36.2 clockwise rotation, in northern part of Haymana Basin 3.1 counter-clockwise and in the southern part 21.2 clockwise rotations took place.

During the Eocene-Oligocene interval amount of rotation was 39.3° clockwise sense in Kırkkale-Bala, 6.4° clockwise in Tuzgölü, 36.2° clockwise in Alcı-Orhaniye, - 3.1° counter-clockwise in the northern part of Haymana and 21.2 clockwise in the southern part of the Haymana basin.

The rotation amounts during the Miocene is as follows; Kırkkale-Alcı Basin 34.4°, clockwise, Tuz Gölü Basin 1.5° clockwise, Alcı-Orhaniye Basin 22.3° counter-clockwise, in the northern part of Haymana Basin 19.3° clockwise and in the southern part of Haymana Basin 6.3° clockwise rotations took place.

The largest Pliocene rotation took place in the northern part of Haymana Basin which is -29.5° (counterclockwise). Similarly, Tuzgölü and Alcı-Orhaniye basins were also rotated counterclockwise during the Pliocene time interval (Table 3.3) while overall Hayman Basin and its southern part rotated around 10.5 and 17.2° clockwise respectively. This implies that vertical axis rotations in the region continued until Pliocene and possibly still continuing.

3.6. Conclusions

Obtained results have shown that there has been significant amount of rotations in the region almost each time interval and each basin.

During the late Cretaceous the largest rotations took place in Alcı-Orhaniye Basin and it was as high as -96° (counter-clockwise). The least rotation took place in the Tuz Gölü Basin and it is around 5.5 ° clockwise senses which is an insignificant amount. The other areas rotated both clockwise and counter-clockwise around 15-25°.

Table 3.3. Rotation amounts restored incrementally for each time interval.

Red numbers indicate amount of rotation that took place during corresponding time interval. Positive numbers indicate clockwise while negative numbers indicate counter-clockwise rotations. Positive numbers also corresponds to paleodeclination values while negative values need to be added to (subtracted from) 360° to obtain their paleodeclinations.

During the Paleocene, the largest rotations took place in the Alcı-Orhaniye (36.2° clockwise), Kırıkkale-Bala (-28° counterclockwise) and southern part of Haymana

(21.2° clockwise) basins. Rotations in other basins are relatively low to negligible. The least rotation took place in the northern Part of Haymana Basin and it is around - 3.1° in counter-clockwise sense. Rotations during the Eocene-Oligocene time interval are very large, in almost all basins, except for the southern part of the Haymana Basin where least rotation values obtained (10.8° clockwise). All other basins experienced clockwise and counterclockwise rotations larger than 25°.

The Miocene rotation values are relatively low except for Kırıkkale-Bala Basin where clockwise rotation reaches up to 34.4°, all other basins experienced rotation less than 23°. Rotations in Tuz Gölü, southern part of Haymana and Hayman Basin combined are negligible. Which implies that only northern part Haymana Basin, Kırıkkale-Bala Basin and Alcı-Orhaniye basin experienced rotation during prior to Pliocene. Kırıkkale-Bala basin does not have any Pliocene rotation data. Northern part of Haymana, Alcı-Orhaniye and Tuz Gölü basins experienced counter-clockwise rotations while only southern part of Haymana Basin experienced clockwise rotation. Clockwise rotation of combined data of overall Haymana Basin is possibly is an artifact of statistical operations. It seems that the data from southern part dominates over the northern part and combined results produced 10.5 ° clockwise rotation.

In conclusion, there has been very large amounts of rotations in all senses and almost in all time intervals and are changed continuously over time. This implies that rotational deformation of the study area has been a continuous process since the Late Cretaceous until recently.

CHAPTER 4

CONCLUSIONS

This study provides a very comprehensive and detailed paleomagnetic and AMS data from the Late Cretaceous to Pliocene time interval mainly from the sedimentary infill of the central Anatolian basins that centered around the Haymana Basin. The other basins include Alcı-Orhaniye, Kırıkkale-Bala and Tuzgölü basins which interrelated and laterally transitional with the Haymana Basin.

These basins straddle the three sutures zones which form a triple junction at the eastern margin of the Haymana Basin, SW and NW margins of Kırıkkale-Bala and Tuzgölü basins, respectively. The Haymana Basin straddles the İzmir-Ankara segment of the İzmir-Ankara-Erzincan Suture Zone while, Kırıkkale-Bala Basin demarcates the Ankara-Erzincan segment of the İzmir-Ankara-Erzincan Suture Zone and Tuzgölü basin is located along the Intra-Tauride Suture Zone.

The study was conducted on by paleomagnetic sampling in 119 sites distributed homogeneously over the study area both temporally and spatially. In these sites more than 4500 samples were collected and measured for both ChRM vector and Anisotropy of Magnetic Susceptibility (AMS) vectors. The majority of the samples are collected from sedimentary rocks ranging in age from late Cretaceous to Pliocene.

Nearly 90% of the measured specimens provided reliable results which are used to investigate the rotational history of the Haymana and adjacent basins including to the Kırıkkale-Bala, Tuz Gölü, and Alcı-Orhaniye basins.

In addition to ChRM results for vertical axes rotations, the AMS results provided deformation history of the study are based on the magnetofabric characteristics of the measured samples.

The major findings of this research are summarized below.

Paleomagnetic studies revealed that;

1. The studied basins and related suture zones are rotated spatially and temporally both clockwise and counter-clockwise (back and forth) since the late Cretaceous continuously.
2. One of the most important outcome of this study is related to the geometry and position of these basins and hence the suture zones. In paleogeographical maps and palinspastic reconstructions, in the literature, the İzmir-Ankara-Erzincan Suture zone is generally envisaged as E-W belt along which the Neotethys ocean subducted northwards below Pontides. Its complete consumption and obliteration is followed by collision of Taurides into the Pontides from south to north along an E-W oriented suture zone. However, the results of this study have shown that the orientation of the suture İzmir-Ankara and Intra-Tauride zones and possibly also the late Cretaceous configuration of the trench was oriented N-S, contrary to what is known previously. In addition, the longer axes of all the basins were oriented N-S during the late Cretaceous and Tuzgölü and Kırıkkale-Bala basins were collinear while Haymana and Alcı-Orhaniye Basins were collinear.
3. The largest rotation took place at the end of Cretaceous in the Alcı-Orhaniye Basin and it was as high as -96° . The other major rotations took place during the Eocene-Oligocene interval and reached up to 71° in Alcı-Orhaniye and 30.6° in Haymana, 39.3° in Kırıkkale-Bala basins. End Paleocene and end Miocene rotations are relatively low except for Alcı-Orhaniye (36.2°) and Kırıkkale-Bala (-28°).
4. The largest Pliocene rotation took place in the northern part of Haymana basin (-29.5°).
5. Rotations along the İzmir-Ankara-Erzincan Suture Zone and the studied basins continued until the recently

The AMS studies revealed that

6. The AMS vectors are related to tectonic deformation and can be used as strain markers. The minimum AMS vector corresponds to maximum principal contraction axis ($k_{\min}$) which is the compaction component of the

sediments, whereas the intermediate axis (k_{int}) corresponds to the major tectonic contraction direction while k_{max} corresponds to principal stretching direction.

7. Based on this assumption late Cretaceous is characterized by multidirectional contraction and extension in different parts of the study area. Whereas, Paleocene is characterized generally by NW-SE directed extension in almost in all areas.
8. Eocene-Oligocene is dominated by NW-SE contraction possible due to indentation of Kırıkkale-Keskin Block into the Kırıkkale-Bala and Alcı-Orhaniye basins, while the Tauride Block squeezed the Tuz Gölü and Haymana basins simultaneously.
9. Miocene is characterized by NW-SE compression in the eastern part of the study area and NE-SW and N-S compression in the western part of the study area.
10. Pliocene is characterized by WNW-ESE compression in the south while it is dominated by NE-SW compression in the Alcı-Orhaniye Basin in the north.
11. There is a very prominent boundary that separates the domains with similar AMS vector orientations. This boundary corresponds to Dereköy-Hirfanlı Fault Zone and was proposed by Lefebvre et al. (2013) and its eastern extension is delineated in this study.

This study successfully applied integration of paleomagnetic and AMS results in unravelling the deformation history as well as spatial and temporal evolution of central Anatolian basins and associated Neotethyan Sutures.

SUPPLEMENTARY A

Up. Cretaceous to Paleocene paleomagnetic site explanations, critical measurement values and mean results.

<i>Site No</i>	<i>Lithology, Age and Stratigraphy</i>	<i>Sample Numbers</i>	<i>Demagnetization</i>	<i>Initial and Isolated intensities</i>	<i>GC and Set Points</i>	<i>Results</i>
R 1	Paleocene in age, bluish to beige, whitish color of fine grain marl. All samples were taken within approximately four meters of stratigraphy.	56 samples were drilled, 34 specimens were demagnetized via AF and TH	5 specimens TH, 23 specimens AF 6 specimens were combined measured	Initial intensities between 200-500 $\mu\text{A/m}$. Isolated ranges about 200°C - 450 °C or between 150 °C plus 15 mT and 40 mT	27 specimens GC and 3 specimens Set Point	ChRM (N=30) result is D= 82 °, I= 52°. 12 specimens of them get magnetized as a reverse polarity.
R 2	Paleogene in age and reddish to brown color, fine grain mudstone, mixed clay and sandstone material within approximately 5 meters sedimentary thickness.	Total 30 number of samples were taken and those 26 samples were demagnetized	4 specimens TH, 17 specimens AF, 5 specimens were combine measured.	Lower level, initial intensities between 25 $\mu\text{A/m}$ -80 $\mu\text{A/m}$, upper level show the intensities between 175-600 $\mu\text{A/m}$	12 specimens GC and 14 specimens selected as a Set Point	ChRM (N=25) result is D=35.4°, I= 58.9°. Inclination value is similar with the present day-field inclination.
R 10	Permian in age and dark to blue color, limestone material approximately in 5 meters thickness.	17 samples were drilled, 17 specimens were demagnetized via AF	17 specimens were measured AF	Initial intensities between 250-800 $\mu\text{A/m}$. Isolated ranges about between 8 mT and 50 mT	7 specimens GC and 10 specimens selected as a Set Point	ChRM (N=16) result is D=28.5°, I= 49.5°. All specimens normally magnetized.

R 11	Up. Paleocene-Eocene in age and yellow to green, fine-medium grain sandstone material approximately in 12 meters thickness. (Kirkkavak Formation)	24 samples were drilled, 18 specimens were demagnetized via AF and TH	4 specimens TH,9 specimens AF, 5 specimens were measured combine	Initial intensities between ~7500-15000 μ A/m. Isolated ranges about 220°C - 430°C or between 150°C plus 30 mT and 80 mT	All specimens interpreted without GC	ChRM (N=16) result is D=301.2°, I= 61.6°. All specimens normally magnetized.
R 12	Up. Paleocene-Eocene in age and yellow to green, fine-medium grain sandstone material approximately in 12 meters thickness. (Kirkkavak Formation)	27 samples were drilled, 18 specimens were demagnetized via AF and TH	4 specimens TH,8 specimens AF, 6 specimens were measured combine	Initial intensities between ~10000-30000 μ A/m. Isolated ranges about 320°C - 580°C or between 150°C plus 30 mT and 80 mT	All specimens interpreted without GC	ChRM (N=18) result is D=292.7°, I= 50°. There are four reversely magnetized specimens.
R 20	Paleocene in age white color, limestone material approximately in 3 meters thickness. Caldag formation.	30 samples were drilled, 20 specimens were demagnetized via AF and TH	4 specimens TH,10 specimens AF, 6 specimens were measured combine	Initial intensities between 50-700 μ A/m. Isolated ranges about 230°C -380°C or between 150°C plus 20 mT and 60 mT	All specimens interpreted without GC	ChRM (N=11) result is D=125.8°, I= - 46.4°. There are 11 reversely magnetized specs.
R 21	Up. Cretaceous in age dark green to blue color, clay, sandy-mudstone material approximately in 4 meters thickness. Haymana formation.	28 samples were drilled, 20 specimens were demagnetized via AF and TH	4 specimens TH,9 specimens AF, 7 specimens were measured combine	Initial intensities between 5000- 22000 μ A/m. Isolated ranges about 230°C -650°C or between 150°C plus 20 mT and 70 mT	All specimens interpreted without GC	ChRM (N=18) result is D=309.4°, I= 55.9°. All specimens normally magnetized.

R 22	Mid. Paleocene-Eocene in age yellow to green color, sandstone material approximately in 3 meters thickness. Kirkkavak formation.	24 samples were drilled, 20 specimens were demagnetized via AF and TH	4 specimens TH, 10 specimens AF, 6 specimens were measured combine	Initial intensities between 10000- 40000 μ A/m. Isolated ranges about 230°C -650°C or between 150°C plus 25 mT and 70 mT	5 specimens GC and 11 specimens selected as a Set Point	ChRM (N=16) result is D=127.9°, I= -16.2°. All specimens reversely magnetized.
R 25	Mid. Paleocene-Eocene in age yellow to green color, sandstone material approximately in 4 meters thickness. Kirkkavak formation.	18 samples were drilled, 18 specimens were demagnetized via AF and TH	4 specimens TH, 8 specimens AF, 6 specimens were measured combine	Initial intensities between 1400- 6000 μ A/m. Isolated ranges about 230°C -560°C or between 150°C plus 25 mT and 70 mT	15 specimens GC and 3 specimens selected as a Set Point	ChRM (N=18) result is D=129.4°, I= -20.9°. All specimens reversely magnetized.
R 34	Paleocene in age white color, limestone material approximately in 3 meters thickness. Caldag formation.	20 samples were drilled, 19 specimens were demagnetized via AF and TH	4 specimens TH, 9 specimens AF, 6 specimens were measured combine	Initial intensities between 50- 500 μ A/m. Isolated ranges about 80°C-300°C or between 150°C plus 10 mT and 30 mT	15 specimens GC and 1 specimens selected as a Set Point	ChRM (N=16) result is D=324.4°, I= 60.2°. There are 3 reversely magnetized specimens.
R 36	Mid. Paleocene-Eocene in age yellow to green color, sandstone material approximately in 5 meters thickness. Kirkkavak formation.	26 samples were drilled, 20 specimens were demagnetized via AF and TH	4 specimens TH, 10 specimens AF, 6 specimens were measured combine	Initial intensities between 50- 500 μ A/m. Isolated ranges about 80°C-225°C or between 150°C plus 8 mT and 30 mT	14 specimens GC and 6 specimens selected as a Set Point	ChRM (N=20) result is D=252.1°, I= -56.6°. All specimens reversely magnetized.
R 38	Up. Cretaceous in age dark green to blue color, clay, sandy-mudstone material approximately	24 samples were drilled, 20 specimens were	4 specimens TH, 10 specimens AF, 6 specimens were	Initial intensities between 1100- 2200 μ A/m. Isolated ranges about 80°C-450°C or	All specimens interpreted without GC	ChRM (N=20) result is D=299.8°, I= 55.1°. All specimens

	in 6 meters thickness. Haymana formation.	demagnetized via AF and TH	measured combine	between 150°C plus 24 mT and 50 mT		normally magnetized.
R 39	Paleocene in age yellow to green color sandstone, material approximately in 5 meters thickness. Yesilyurt formation.	21 samples were drilled, 20 specimens were demagnetized via AF and TH	4 specimens TH, 10 specimens AF, 6 specimens were measured combine	Initial intensities between 200- 600 μ A/m. Isolated ranges about 180°C-500°C or between 150°C plus 6 mT and 35 mT	All specimens interpreted without GC	ChRM (N=11) result is D=224.1°, I= 48.3°. All specimens normally magnetized.
R 41	Up. Cretaceous in age dark green to blue color, clay, sandy-mudstone material approximately in 8 meters thickness. Haymana formation.	22 samples were drilled, 22 specimens were demagnetized via AF and TH	4 specimens TH, 12 specimens AF, 6 specimens were measured combine	Initial intensities between 6500- 20000 μ A/m. Isolated ranges about 420°C-650°C or between 150°C plus 40 mT and 80 mT	17 specimens GC and 4 specimens selected as a Set Point	ChRM (N=21) result is D=148.9°, I= - 48.5°. All specimens reversely magnetized.
R 43	Mid. Paleocene-Eocene in age yellow to green color, sandstone material approximately in 3 meters thickness. Kirkkavak formation.	16 samples were drilled, 15 specimens were demagnetized via AF and TH	4 specimens TH, 5 specimens AF, 6 specimens were measured combine	Initial intensities between 500- 2000 μ A/m. Isolated ranges about?	no set points and no GC	No result, because of remagnetization or big overprint over
R 48	Paleocene in age green to brown color, sandstone material approximately in 3 meters thickness.	24 samples were drilled, 21 specimens were demagnetized via AF and TH	4 specimens TH, 11 specimens AF, 6 specimens were measured combine	Initial intensities between 150- 400 μ A/m. Isolated ranges about 150°C-420°C or between 150°C plus 20 mT and 60 mT	All specimens interpreted without GC	ChRM (N=15) result is D=229.4°, I= - 52.6°. All specimens reversely magnetized.

R 53	Mid. Paleocene-Eocene in age yellow to green color, sandstone material approximately in 3 meters thickness. Kartal-Kirkkavak boundary.	25 samples were drilled, 21 specimens were demagnetized via AF and TH	4 specimens TH, 11 specimens AF, 6 specimens were measured combine	Initial intensities between 3000- 18000 $\mu\text{A/m}$. Isolated ranges about 80°C-300°C or between 150°C plus 10 mT and 40 mT	19 specimens GC and 2 specimens selected as a Set Point	ChRM (N=21) result is D=33.4°, I= 35.2°. All specimens normally magnetized.
R 55	Up. Cretaceous in age dark green to blue color, clay, sandy-mudstone material approximately in 12 meters thickness. Haymana formation.	26 samples were drilled, 21 specimens were demagnetized via AF and TH	4 specimens TH, 11 specimens AF, 6 specimens were measured combine	Initial intensities between 1000- 2000 $\mu\text{A/m}$. Isolated ranges about 100°C-400°C or between 150°C plus 20 mT and 80 mT	All specimens interpreted without GC	ChRM (N=21) result is D=321.3°, I= 50°. All specimens normally magnetized.
R 56	Paleocene in age red to pink color sandstone-clay material approximately in 7 meters thickness. Kartal formation.	20 samples were drilled, 23 specimens were demagnetized via AF and TH	4 specimens TH, 13 specimens AF, 6 specimens were measured combine	Initial intensities between 1200- 3000 $\mu\text{A/m}$. Isolated ranges about 100°C-450°C or between 150°C plus 20 mT and 80 mT	14 specimens GC and 9 specimens selected as a Set Point	ChRM (N=23) result is D=135.3°, I= 61.2°. All specimens normally magnetized.
R 59	Paleocene in age red to pink color sandstone-clay material approximately in 5 meters thickness. Kartal formation.	23 samples were drilled, 21 specimens were demagnetized via AF and TH	4 specimens TH, 11 specimens AF, 6 specimens were measured combine	Initial intensities between 800- 1100 $\mu\text{A/m}$. Isolated ranges about 80°C-350°C or between 150°C plus 45 mT and 90 mT	All specimens interpreted without GC	ChRM (N=17) result is D=61.2°, I= 68.2°. All specimens normally magnetized.
R 60	Paleocene in age yellow to green color sandstone-mudstone material approximately in 6 meters	15 samples were drilled, 15 specimens were	4 specimens TH, 5 specimens AF, 6 specimens were	Initial intensities between 800- 1000 $\mu\text{A/m}$. Isolated ranges about 250°C-420°C or	All specimens interpreted without GC	ChRM (N=14) result is D=122.3°, I= - 46.3°. All specimens

	thickness.	demagnetized via AF and TH	measured combine	between 150°C plus 45 mT and 80 mT		reversely magnetized.
R 61	Paleocene in age yellow to green color sandstone-mudstone material approximately in 13 meters thickness.	17 samples were drilled, 16 specimens were demagnetized via AF and TH	4 specimens TH, 6 specimens AF, 6 specimens were measured combine	Initial intensities between 4500- 7000 μ A/m. Isolated ranges about 250°C-420°C or between 150°C plus 30 mT and 60 mT	14 specimens GC and 2 specimens selected as a Set Point	ChRM (N=16) result is D=46.2°, I= 26.9°. There are 4 specimens reversely magnetized.
R 62	Paleocene in age yellow to green color sandstone-mudstone material approximately in 3 meters thickness.	17 samples were drilled, 16 specimens were demagnetized via AF and TH	4 specimens TH, 6 specimens AF, 6 specimens were measured combine	Initial intensities between 10200- 67000 μ A/m. Isolated ranges about 150°C-530°C or between 150°C plus 5 mT and 45 mT	9 specimens GC and 3 specimens selected as a Set Point	ChRM (N=12) result is D=56.0°, I= 36.5°. There are 4 specimens reversely magnetized.
R 64	Paleocene in age yellow to green color sandstone-mudstone material approximately in 2 meters thickness.	18 samples were drilled, 18 specimens were demagnetized via AF and TH	4 specimens TH, 6 specimens AF, 6 specimens were measured combine	Initial intensities between 400- 3300 μ A/m. Isolated ranges about 180°C-420°C or between 150°C plus 10 mT and 30 mT	15 specimens GC and 2 specimens selected as a Set Point	ChRM (N=17) result is D=4.3°, I= 49.5°. There are 12 specimens reversely magnetized.
R 65	Up. Cretaceous in age yellow to green color sandstone-mudstone material approximately in 11 meters thickness.	27 samples were drilled, 21 specimens were demagnetized via AF and TH	4 specimens TH, 11 specimens AF, 6 specimens were measured combine	Initial intensities between 5000- 127000 μ A/m. Isolated ranges about 180°C-450°C or between 150°C plus 12 mT and 50 mT	21 specimens GC and 1 specimens selected as a Set Point	ChRM (N=20) result is D=74°, I= 46.2°. There are 10 specimens reversely magnetized.

R 67	Up. Cretaceous-Paleogene age yellow to red color sand-mudstone material approximately in 8 meters thickness.	25 samples were drilled, 21 were demagnetized via AF and TH	4 spec. TH, 11 spec. AF, 6 spec. were measured combine	Initial inten. between 3000-8500 μ A/m. Isolated ranges about 80°C-300°C or 20 mT and 90 mT	All specimens interpreted without GC	ChRM (N=21) result D=352°, I= 68.9°. All specimens normally magnetized.
R 68	Paleocene in age yellow to green color sandstone-mudstone material approximately in 4 meters thickness.	20 samples were drilled, 20 specimens were demagnetized via AF and TH	4 specimens TH, 10 specimens AF, 6 specimens were measured combine	Initial intensities between 1500- 17000 μ A/m. Isolated ranges about 80°C-650°C or between 150°C plus 40 mT and 90 mT	6 specimens GC and 14 specimens selected as a Set Point	ChRM (N=20) result is D=44.5°, I= 44.9°. All specimens normally magnetized.
R 69	Paleocene in age yellow to green color sandstone-mudstone material approximately in 5 meters thickness.	21 samples were drilled, 19 specimens were demagnetized via AF and TH	4 specimens TH, 9 specimens AF, 6 specimens were measured combine	Initial intensities between 500- 1700 μ A/m. Isolated ranges about 80°C-300°C or between 150°C plus 30 mT and 80 mT	All specimens interpreted without GC	ChRM (N=19) result is D=71.5°, I= 52.4°. All specimens normally magnetized.
R 73	Up. Cretaceous in age yellow to green color sandstone-mudstone material approximately in 3 meters thickness.	17 samples were drilled, 17 specimens were demagnetized via AF and TH	4 specimens TH, 7 specimens AF, 6 specimens were measured combine	Initial intensities between 7000- 21000 μ A/m. Isolated ranges about 180°C-500°C or between 150°C plus 20 mT and 50 mT	All specimens interpreted without GC	ChRM (N=10) result is D=242.3°, I= - 41.9°. All specimens reversely magnetized.
R 74	Paleocene in age yellow to green color sandstone-mudstone material approximately in 8 meters thickness.	16 samples were drilled, 15 specimens were demagnetized via	4 specimens TH, 5 specimens AF, 6 specimens were measured combine	Initial intensities between 2500- 5200 μ A/m. Isolated ranges about 80°C-450°C or between 150°C plus 20 mT	All specimens interpreted without GC	ChRM (N=15) result is D=324.3°, I= 37.3°. All specimens normally magnetized.

		AF and TH			and 80 mT		
R 75	Paleocene in age yellow to green color sandstone-mudstone material approximately in 10 meters thickness.	17 samples were drilled, 16 specimens were demagnetized via AF and TH	4 specimens TH, 6 specimens AF, 6 specimens were measured combine	Initial intensities between 3000- 13000 μ A/m. Isolated ranges about 225°C-610°C or between 150°C plus 35 mT and 90 mT	All specimens interpreted without GC	ChRM (N=16) result is D=232.6°, I= 53.1°. All specimens normally magnetized.	
R 76	Paleocene in age yellow to green color sandstone-mudstone material approximately in 6 meters thickness.	22 samples were drilled, 22 specimens were demagnetized via AF and TH	4 specimens TH, 12 specimens AF, 6 specimens were measured combine	Initial intensities between 1000- 2700 μ A/m. Isolated ranges about 120°C-320°C or between 150°C plus 6 mT and 45 mT	All specimens interpreted without GC	ChRM (N=22) result is D=353.5°, I= 37.3°. All specimens normally magnetized.	
R 77	Paleocene in age yellow to green color sandstone-mudstone material approximately in 5 meters thickness.	25 samples were drilled, 18 specimens were demagnetized via AF and TH	4 specimens TH, 6 specimens AF, 6 specimens were measured combine	Initial intensities between 500- 3600 μ A/m. Isolated ranges about 120°C-380°C or between 150°C plus 3 mT and 33 mT	13 specimens GC and 5 specimens selected as a Set Point	ChRM (N=18) result is D=77.2°, I= 46.3°. There are 7 specimens reversely magnetized.	
R 83	Up. Cretaceous in age yellowish color sandstone material approximately in 12 meters thickness.	33 samples were drilled, 21 specimens were demagnetized via AF and TH	4 specimens TH, 11 specimens AF, 6 specimens were measured combine	Initial intensities between 12000- 63000 μ A/m. Isolated ranges about 120°C-560°C or between 150°C plus 4 mT and 70 mT	All specimens interpreted without GC	ChRM (N=21) result is D=14.3°, I= 42.4°. All specimens normally magnetized.	
RN2	Paleocene in age red to pink color sandstone-clay material	14 samples were drilled, 14	4 specimens TH, 6 specimens AF, 6	Initial intensities between 1300- 2500 μ A/m. Isolated	8 specimens GC and 2 specimens	ChRM (N=10) result is D=124.2°, I= 62.6°.	

	approximately in 7 meters thickness. Kartal formation.	specimens were demagnetized via AF and TH	specimens were measured combine	ranges about 400°C-650°C or between 150°C plus 40 mT and 80 mT	or selected as a Set Point	All specimens normally magnetized.
RN3	Mid. Paleocene-Eocene in age yellow to green color, sandstone material approximately in 3 meters thickness. Kirkkavak formation.	13 samples were drilled, 20 specimens were demagnetized via AF and TH	4 specimens TH, 10 specimens AF, 6 specimens were measured combine	Initial intensities between 1000- 2100 μ A/m. Isolated ranges about 320°C-520°C or between 150°C plus 8 mT and 40 mT	18 specimens GC and 1 specimens or selected as a Set Point	ChRM (N=18) result is D=129.8°, I= 65.3°. All specimens normally magnetized.
RN6	Paleocene in age yellow to green color sandstone-claystone material approximately in 20 meters thickness.	20 samples were drilled, 21 specimens were demagnetized via AF and TH	4 specimens TH, 11 specimens AF, 6 specimens were measured combine	Initial intensities between 3000- 15000 μ A/m. Isolated ranges about 350°C-500°C or between 150°C plus 20 mT and 50 mT	21 specimens GC and 1 specimens or selected as a Set Point	ChRM (N=22) result is D=184.2°, I=-34.4°. All specimens reversely magnetized.
RN9	Paleocene in age yellow to green color sandstone-claystone material approximately in 12 meters thickness.	22 samples were drilled, 20 specimens were demagnetized via AF and TH	4 specimens TH, 10 specimens AF, 6 specimens were measured combine	Initial intensities between 500- 3500 μ A/m. Isolated ranges about 150°C-550°C or between 150°C plus 12 mT and 70 mT	All specimens interpreted without GC	ChRM (N=20) result is D=203.6°, I=-35.9°. All specimens reversely magnetized.
RN10	Paleocene in age yellow to green color sandstone-mudstone material approximately in 5 meters thickness.	20 samples were drilled, 19 specimens were demagnetized via AF and TH	5 specimens TH, 14 specimens were measured AF	Initial intensities between 100- 600 μ A/m. Isolated ranges about 330°C-500°C or between 150°C plus 9 mT and 50 mT	6 specimens GC and 4 specimens or selected as a Set Point	ChRM (N=22) result is D=55.5°, I= 61.6°. All specimens normally magnetized.

RN11	Paleocene in age yellow to green color sandstone-mudstone material approximately in 7 meters thickness.	20 samples were drilled, 20 specimens were demagnetized via AF and TH	5 specimens TH, 15 specimens were measured AF	Initial intensities between 500- 3600 μ A/m. Isolated ranges about 120°C-380°C or between 150°C plus 3 mT and 33 mT	14 specimens GC and 5 specimens selected as a Set Point	ChRM (N=18) result is D=117°, I=-43.8°. All specimens reversely magnetized.
RN12	Paleocene in age yellowish color sandstone material approximately in 12 meters thickness.	25 samples were drilled, 17 specimens were demagnetized via AF and TH	5 specimens TH, 12 specimens were measured AF	Initial intensities between 200- 3000 μ A/m. Isolated ranges about 120°C-370°C or between 150°C plus 4 mT and 60 mT	All specimens interpreted without GC	ChRM (N=21) result is D=26.3°, I= 35.6°. All specimens normally magnetized.
OA	Up. Cretaceous in age granitoid in 12 meters thickness.	20 samples were drilled, 20 specimens were demagnetized via AF and TH	All specimens were measured AF	Initial intensities between 500- 55000 μ A/m. Isolated ranges between 4 mT and 100 mT	All specimens interpreted without GC	ChRM (N=21) result is D=14.3°, I= 42.4°. All specimens normally magnetized.
SEC2	Mid. Paleocene-Eocene in age red, yellow to green color, sandstone-clay, and mudstone material approximately in 700 meters thickness. Kartal-Kirkkavak boundary.	624 samples were drilled, 416 specimens were demagnetized via AF and TH	208 specimens TH, 208 specimens AF were measured	Initial intensities between ~10000-15000 μ A/m. Isolated ranges about 200°C -650°C or between 15 mT and 60 mT	All specimens interpreted without GC	ChRM (N=196) result is D=314.1°, I= 56°. There are normal and reverse magnetization
SEC3	Up. Cretaceous in age dark green to blue color, clay, sandy-	202 samples were drilled, 202	101 specimens TH, 101 specimens AF	Initial intensities between ~2000-50000 μ A/m.	All specimens interpreted without GC	ChRM (N=103) result is D=279.7°, I= 61.9°.

	mudstone material approximately in 288 meters thickness. Haymana formation.	specimens were demagnetized via AF and TH	were measured	Isolated ranges about 200°C - 580°C or between 15 mT and 80 mT	GC	There are normal and reverse magnetization
SEC4	Paleocene in age yellow to green color sandstone-marl, material approximately in 64 meters thickness. Yeşilyurt formation.	64 samples were drilled, 64 specimens were demagnetized via AF and TH	32 specimens TH, 32 specimens AF were measured	Initial intensities between ~150-1400 µA/m. Isolated ranges about 200°C - 450°C or between 8 mT and 50 mT	All specimens interpreted without GC	ChRM (N=14) result D=337.1°, I= 17.6°. All specimens normally magnetized.
K-T	Cretaceous-Paleogene boundary limestone-marl-sandstone-mudstone material approximately in 35 meters thickness.	20 samples were drilled, 20 specimens were demagnetized via AF	20 specimens were measured AF	Initial intensities between 450- 12500 µA/m. Isolated ranges between 10 mT and 80 mT	All specimens interpreted without GC	ChRM (N=20) result D=236.6°, I= 51.6°. There are 7 specimens reversely magnetized.
RH 1	Up. Cretaceous in age dark green to blue color, clay-mudstone material approximately in 9 meters thickness. Haymana formation.	Total 45 number of samples were taken and those 24 samples were demagnetized	4 specimens TH, 15 specimens AF, 5 specimens were combine measured.	Initial intensities between 2700-9000 µA/m. Isolated ranges about 180°C -500°C or between 150°C plus 20 mT and 80 mT	All specimens interpreted without GC	ChRM (N=24) result D=281.7°, I= 49.9°. All specimens normally magnetized.
RH 2	Up. Cretaceous in age dark green to blue color, clay-mudstone material approximately in 11 meters thickness. Haymana formation.	Total 57 number of samples were taken and those 26 samples were demagnetized	4 specimens TH, 17 specimens AF, 5 specimens were combine measured.	Initial intensities between 1200-3200 µA/m. Isolated ranges about 180°C -500°C or between 150°C plus 40 mT and 80 mT	All specimens interpreted without GC	ChRM (N=25) result D=329.4°, I= 28.5°. All specimens normally magnetized.

RY 1	Paleogene in age and reddish to green color, fine grain mudstone-sandstone material within approximately 6 meters sedimentary thickness.	Total 60 number of samples were taken and those 22 samples were demagnetized	4 specimens TH, 13 specimens AF, 5 specimens were combine measured.	Initial intensities between 1200-3200 μ A/m. Isolated ranges about 180°C -480°C or between 150°C plus 40 mT and 80 mT	All specimens interpreted without GC	ChRM (N=22) result is $D=323.7^\circ$, $I=27.4^\circ$. All specimens normally magnetized.

SUPPLEMENTARY B

Eocene Pliocene paleomagnetic site explanations, critical measurement values and mean results.

Site No	Lithology, Age and Stratigraphy	Sample Numbers	Demagnetization	Initial and Isolated intensities	GC and Set Points	Results
R 3	Up. Miocene-Pliocene in age brown to yellow color, mudstone material approximately in 3 meters thickness.	Total 35 number of samples were taken and those 26 samples were demagnetized	4 specimens TH, 17 specimens AF, 5 specimens were combine measured.	Initial intensities between 40-162 μ A/m. Isolated ranges about 120°C -300°C or between 150°C plus 5 mT and 40 mT	6 specimens GC and 17 specimens selected as a Set Point	ChRM (N=23) result is D=29.5°, I= 65°. All specimens normally magnetized.
R 4	Lower-Middle Miocene in age, brown color of fine grain mudstone. All samples were taken within approximately 2 meters of stratigraphy.	Total 46 number of samples were taken and those 34 samples were demagnetized	4 specimens TH, 25 specimens AF, 5 specimens were combine measured.	Initial intensities between 240-550 μ A/m. Isolated ranges about 150°C -390°C or between 150°C plus 15 mT and 80 mT	All specimens interpreted without GC	ChRM (N=29) result is D=319.7°, I= 52.9°. All specimens normally magnetized.
R 5	Up. Miocene-Pliocene in age reddish to yellow color, mudstone-marl material approximately in 3 meters thickness.	Total 23 number of samples were taken and those 18 samples were demagnetized.	4 specimens TH, 9 specimens AF, 5 specimens were combine measured.	Initial intensities between 200-2000 μ A/m. Isolated ranges about 150°C -390°C or between 150°C plus 5 mT and 50 mT.	5 specimens GC and 7 specimens selected as a Set Point.	ChRM (N=11) result is D=203.4°, I= -43.1°. All specimens reversely magnetized.

R 13	Middle Miocene in age and dark brown color, fine grain andesite, approximately in 11 meters thickness.	22 samples were drilled, 18 specimens were demagnetized via AF and TH	4 specimens TH, 8 specimens AF, 6 specimens were measured combine	Initial intensities between 550000- 120000 $\mu\text{A/m}$. Isolated ranges about 80°C - 580°C or between 150°C plus 10 mT and 100 mT	All specimens interpreted without GC	ChRM (N=18) result is D=1.6°, I= 57.6°. All specimens normally magnetized.
R 14	Lower-Mid. Miocene in age and purple to white color, marl material approximately in 3 meters thickness.	14 samples were drilled, 8 specimens were demagnetized via AF	8 specimens AF	Initial intensities between 20-80 $\mu\text{A/m}$. Isolated ranges?	all scattered data	Low Intensities.
R 15	Lower-Mid. Miocene in age and purple to white color, marl material approximately in 3 meters thickness.	28 samples were drilled, 10 specimens were demagnetized via AF and TH	3 specimens TH, 7 specimens combined	Initial intensities between 100000- 200000 $\mu\text{A/m}$. Isolated ranges?	all scattered data	Lightning.
R 16	Lower-Mid. Miocene in age grey to white color, Limestone, marl material approximately in 3 meters thickness.	29 samples were drilled, 18 specimens were demagnetized via AF and TH	4 specimens TH, 8 specimens AF, 6 specimens were measured combine	Initial intensities between 100- 500 $\mu\text{A/m}$. Isolated ranges about 80°C -280°C or between 150°C plus 10 mT and 30 mT	14 specimens GC and 2 specimens selected as a Set Point	ChRM (N=16) result is D=207.5°, I= -37.2°. There are twelve reversely magnetized specimens.

R 17	Lower-Mid. Miocene in age yellowish to purple color, sandstone, mudstone material approximately in 4 meters thickness.	21 samples were drilled, 18 specimens were demagnetized via AF and TH	4 specimens TH, 8 specimens AF, 6 specimens were measured combine	Initial intensities between 1500-18000 μ A/m. Isolated ranges about 80°C -330°C or between 150°C plus 20 mT and 50 mT	15 specimens GC and 2 specimens selected as a Set Point	ChRM (N=17) result is D=55.5°, I= 63.2°. There are 14 reversely magnetized specimens.
18	Up. Miocene-Pliocene in age purple to white color, limestone material approximately in 2 meters thickness.	33 samples were drilled, 20 specimens were demagnetized via AF and TH	4 specimens TH, 10 specimens AF, 6 specimens were measured combine	Initial intensities between 3000- 5000 μ A/m. Isolated ranges about 150°C -500°C or between 150°C plus 20 mT and 65 mT	8 specimens GC and 12 specimens selected as a Set Point	ChRM (N=19) result is D=344.5°, I= 43.4°. There are 8 reversely magnetized specimens.
R 19	Up. Miocene-Pliocene in age reddish to yellow color, limestone material approximately in 3 meters thickness.	27 samples were drilled, 20 specimens were demagnetized via AF and TH	4 specimens TH, 10 specimens AF, 6 specimens were measured combine	Initial intensities between 400- 2200 μ A/m. Isolated ranges about 80°C -280°C or between 150°C plus 10 mT and 40 mT	15 specimens GC and 3 specimens selected as a Set Point	ChRM (N=18) result is D=199.9°, I= -49.4°. There are 14 reversely magnetized specimens.
R 23	Mid. Paleocene-Eocene in age yellow to green color, sandstone material approximately in 2 meters thickness. Kirkkavak formation.	16 samples were drilled, 16 specimens were demagnetized via AF and TH	4 specimens TH, 6 specimens AF, 6 specimens were measured combine	Initial intensities between 10000- 20000 μ A/m. Isolated ranges about?	no set points and no GC	No result, because of demagnetization or big overprint

R 24	Pliocene in age reddish to purple color, marl, mudstone material approximately in 3 meters thickness.	25 samples were drilled, 24 specimens were demagnetized via AF and TH	4 specimens TH, 14 specimens AF, 6 specimens were measured combine	Initial intensities between 5000- 170000 $\mu\text{A/m}$. Isolated ranges about 230°C -560°C or between 150°C plus 25 mT and 70 mT	All specimens interpreted without GC	ChRM (N=20) result is D=153.5°, I= -48.5°. All specimens reversely magnetized.
R 26	Low-Middle Eocene in age yellow to green color, sandstone material approximately in 3 meters thickness. Eskipolatli formation.	29 samples were drilled, 21 specimens were demagnetized via AF and TH	4 specimens TH, 11 specimens AF, 6 specimens were measured combine	Initial intensities between 7000- 45000 $\mu\text{A/m}$. Isolated ranges about 200°C -500°C or between 150°C plus 10 mT and 35 mT	17 specimens GC and 4 specimens selected as a Set Point	ChRM (N=21) result is D=118.2°, I= 67.5°. All specimens normally magnetized.
R 27	Lower-Mid. Miocene in age and yellow to brown color, fine grain marl, sandstone material approximately in 2 meters thickness.	17 samples were drilled, 18 specimens were demagnetized via AF and TH	4 specimens TH, 8 specimens AF, 6 specimens were measured combine	Initial intensities between 30000- 225000 $\mu\text{A/m}$. Isolated ranges about 180°C - 610°C or between 150°C plus 35 mT and 70 mT	All specimens interpreted without GC	ChRM (N=17) result is D=326.9°, I= 49.4°. All specimens normally magnetized.
R 28	Pliocene in age reddish to yellow color, marl, mudstone material approximately in 3 meters thickness.	26 samples were drilled, 20 specimens were demagnetized via AF and TH	4 specimens TH, 10 specimens AF, 6 specimens were measured combine	Initial intensities between 100- 400 $\mu\text{A/m}$. Isolated ranges about 80°C-275°C or between 150°C plus 20 mT and 50 mT	All specimens interpreted without GC	ChRM (N=15) result is D=345.2°, I= 46.4°. There are 1 reversely magnetized specimens.

R 29	Lower-Mid. Miocene in age and yellow to white color, fine grain marl, material approximately in 2 meters thickness.	18 samples were drilled, 17 specimens were demagnetized via AF and TH	4 specimens TH, 7 specimens AF, 6 specimens were measured combine	Initial intensities between 50-200 $\mu\text{A/m}$. Isolated ranges about 80°C-350°C or between 150°C plus 18 mT and 40 mT	All specimens interpreted without GC	ChRM (N=14) result is D=330.3°, I= 49.1°. All specimens normally magnetized.
R 30	Lower-Mid. Miocene in age and yellow to white color, fine grain marl, limestone material approximately in 5 meters thickness.	19 samples were drilled, 19 specimens were demagnetized via AF and TH	4 specimens TH, 9 specimens AF, 6 specimens were measured combine	Initial intensities between 175- 900 $\mu\text{A/m}$. Isolated ranges about 80°C-280°C or between 150°C plus 20 mT and 60 mT	All specimens interpreted without GC	ChRM (N=15) result is D=134.9°, I= -40.9°. There are 13 reversely magnetized specimens.
R 31	Lower-Mid. Miocene in age and reddish to yellow color, fine grain marl, material approximately in 3 meters thickness.	20 samples were drilled, 20 specimens were demagnetized via AF and TH	4 specimens TH, 10 specimens AF, 6 specimens were measured combine	Initial intensities between 17000- 32000 $\mu\text{A/m}$. Isolated ranges about 180°C-580°C or between 150°C plus 20 mT and 60 mT	All specimens interpreted without GC	ChRM (N=15) result is D=349.8°, I= 51.8°. All specimens normally magnetized.
R 32	Up. Miocene-Pliocene in age and white to yellowish color, fine grain marl, material approximately in 3 meters thickness.	32 samples were drilled, 24 specimens were demagnetized via AF and TH	4 specimens TH, 14 specimens AF, 6 specimens were measured combine	Initial intensities between 150- 300 $\mu\text{A/m}$. Isolated ranges about 80°C-300°C or between 150°C plus 20 mT and 50 mT	All specimens interpreted without GC	ChRM (N=24) result is D=4.9°, I= 56.5°. All specimens normally magnetized.

R 33	Low-Middle Eocene in age yellow to red color, sandstone material approximately in 7 meters thickness. Ilginlikdere formation.	17 samples were drilled, 17 specimens were demagnetized via AF and TH	4 specimens TH, 7 specimens AF, 6 specimens were measured combine	Initial intensities between 2000- 15000 μ A/m. Isolated ranges about 80°C-280°C or between 150°C plus 12 mT and 35 mT	13 specimens GC and 4 specimens selected as a Set Point	ChRM (N=17) result is D=16.3°, I= 18.2°. There are 12 reversely magnetized specimens.
R 35	Low-Middle Eocene in age red color sandstone material approximately in 6 meters thickness. Ilginlikdere formation.	25 samples were drilled, 22 specimens were demagnetized via AF and TH	4 specimens TH, 12 specimens AF, 6 specimens were measured combine	Initial intensities between 20000- 36000 μ A/m. Isolated ranges about 300°C-630°C or between 150°C plus 30 mT and 80 mT	15 specimens GC and 7 specimens selected as a Set Point	ChRM (N=22) result is D=287.5°, I= 61.5°. All specimens normally magnetized.
R 37	Pliocene in age yellow to white color, marl, limestone material approximately in 3 meters thickness.	26 samples were drilled, 20 specimens were demagnetized via AF and TH	4 specimens TH, 10 specimens AF, 6 specimens were measured combine	Initial intensities between 50- 200 μ A/m. Isolated ranges about between 150°C plus 8 mT and 30 mT	8 specimens GC and 7 specimens selected as a Set Point	ChRM (N=15) result is D=202.8°, I= -52.2°. There are 12 specimens reversely magnetized.
R 40	Mid. Paleocene-Eocene in age dark green to reddish color, sandstone, claystone material approximately in 6 meters thickness. Kirkkavak formation.	27 samples were drilled, 24 specimens were demagnetized via AF and TH	4 specimens TH, 14 specimens AF, 6 specimens were measured combine	Initial intensities between 2000- 8000 μ A/m. Isolated ranges about 100°C-250°C or between 150°C plus 16 mT and 40 mT	11 specimens GC and 13 specimens selected as a Set Point	ChRM (N=24) result is D=296.3°, I= 57.7°. All specimens normally magnetized.

R 42	Low-Middle Eocene in age yellow- to green color sandstone-clay material approximately in 3 meters thickness. Ilginlikdere formation.	23 samples were drilled, 21 specimens were demagnetized via AF and TH	4 specimens TH, 11 specimens AF, 6 specimens were measured combine	Initial intensities between 2500- 10000 $\mu\text{A/m}$. Isolated ranges about 420°C-650°C or between 150°C plus 40 mT and 90 mT	All specimens interpreted without GC	ChRM (N=13) result is D=52.1°, I= 38.8°. All specimens normally magnetized.
R 44	Low-Middle Eocene in age yellowish to green color sandstone material approximately in 5 meters thickness. Eskipolatli formation.	26 samples were drilled, 21 specimens were demagnetized via AF and TH	4 specimens TH, 11 specimens AF, 6 specimens were measured combine	Initial intensities between 6500- 10000 $\mu\text{A/m}$. Isolated ranges about 350°C-580°C or between 150°C plus 40 mT and 80 mT	All specimens interpreted without GC	ChRM (N=21) result is D=283°, I= -38.9°. All specimens reversely magnetized.
R 45	Mid. Miocene in dark color, pyroclastic material approximately 3 samples in three meters and 7 different levels.	34 samples were drilled, 23 specimens were demagnetized via AF and TH	4 specimen's TH, 13 specimen's AF, 6 specimens were measured combine	Initial intensities between 100000- 350000 $\mu\text{A/m}$. Isolated ranges about 80°C-500°C or between 150°C plus 20 mT and 70 mT	16 specimens GC and 5 specimens selected as a Set Point	ChRM (N=21) result is D=198.9°, I= -44°. All specimens reversely magnetized.
R 46	Mid. Miocene in dark color, pyroclastic material approximately 3 samples in three meters and 7 different levels.	24 samples were drilled, 21 specimens were demagnetized via AF and TH	4 specimens TH, 11 specimens AF, 6 specimens were measured combine	Initial intensities between 150000- 200000 $\mu\text{A/m}$. Isolated ranges about 80°C-300°C or between 150°C plus 20 mT and 40 mT	12 specimens GC and 9 specimens selected as a Set Point	ChRM (N=21) result is D=6°, I= 51°. There are 5 reversely magnetized specimens.

R 47	Low-Middle Eocene in age yellowish to green color sandstone material approximately in 5 meters thickness. Yamak formation.	27 samples were drilled, 21 specimens were demagnetized via AF and TH	4 specimens TH, 11 specimens AF, 6 specimens were measured combine	Initial intensities between 2500- 7000 $\mu\text{A/m}$. Isolated ranges about 150°C-300°C or between 150°C plus 20 mT and 80 mT	All specimens interpreted without GC	ChRM (N=21) result is D=28.3°, I= 65°. All specimens normally magnetized.
R 49	Low-Middle Eocene in age yellowish to green color sandstone-clay material approximately in 5 meters thickness. Eskipolatli formation.	23 samples were drilled, 20 specimens were demagnetized via AF and TH	4 specimens TH, 10 specimens AF, 6 specimens were measured combine	Initial intensities between 2000- 5000 $\mu\text{A/m}$. Isolated ranges about?	no set points and no GC	No result, because of remagnetization or big overprint over
R 50	Pliocene in age yellowish to brown color sandstone-clay material approximately in 3 meters thickness.	20 samples were drilled, 21 specimens were demagnetized via AF and TH	4 specimens TH, 11 specimens AF, 6 specimens were measured combine	Initial intensities between 1300- 9500 $\mu\text{A/m}$. Isolated ranges about 80°C-300°C or between 150°C plus 10 mT and 40 mT	17 specimens GC and 3 specimens selected as a Set Point	ChRM (N=20) result is D=214.1°, I= -56.2°. There are 16 specimens reversely magnetized.
R 51	Pliocene in age yellowish to brown color sandstone-clay material approximately in 4 meters thickness.	20 samples were drilled, 19 specimens were demagnetized via AF and TH	4 specimens TH, 9 specimens AF, 6 specimens were measured combine	Initial intensities between 5000- 30000 $\mu\text{A/m}$. Isolated ranges about 80°C-380°C or between 150°C plus 20 mT and 60 mT	10 specimens GC and 8 specimens selected as a Set Point	ChRM (N=20) result is D=165.1°, I= -38.7°. All specimens reversely magnetized.

R 52	Low-Middle Eocene in age yellowish to green color sandstone material approximately in 4 meters thickness. Eskipolatli formation.	28 samples were drilled, 21 specimens were demagnetized via AF and TH	4 specimens TH, 11 specimens AF, 6 specimens were measured combine	Initial intensities between 6000- 10000 μ A/m. Isolated ranges about 80°C-350°C or between 150°C plus 20 mT and 60 mT	11 specimens GC and 10 specimens selected as a Set Point	ChRM (N=20) result is D=232.3°, I= 54.9°. There are 14 specimens reversely magnetized.
R 54	Low-Middle Miocene in age yellowish to white color marl-sandstone material approximately in 5 meters thickness.	17 samples were drilled, 17 specimens were demagnetized via AF and TH	4 specimens TH, 7 specimens AF, 6 specimens were measured combine	Initial intensities between 2000- 62000 μ A/m. Isolated ranges about 80°C-530°C or between 150°C plus 30 mT and 70 mT	All specimens interpreted without GC	ChRM (N=11) result is D=38.2°, I= 53.4°. There are 3 specimens reversely magnetized.
R 57	Low-Middle Eocene in age yellowish to green color sandstone-clay material approximately in 6 meters thickness. Ilginlikdere formation.	19 samples were drilled, 17 specimens were demagnetized via AF and TH	4 specimens TH, 7 specimens AF, 6 specimens were measured combine	Initial intensities between 2000- 7000 μ A/m. Isolated ranges about 100°C-450°C or between 150°C plus 20 mT and 80 mT	All specimens interpreted without GC	ChRM (N=17) result is D=232.6°, I= 59°. All specimens normally magnetized.
R 58	Low-Middle Eocene in age dark blue color claystone material approximately in 7 meters thickness. Yamak formation.	18 samples were drilled, 18 specimens were demagnetized via AF and TH	4 specimens TH, 8 specimens AF, 6 specimens were measured combine	Initial intensities between 800- 3100 μ A/m. Isolated ranges about 100°C-530°C or between 150°C plus 30 mT and 90 mT	All specimens interpreted without GC	ChRM (N=17) result is D=337.2°, I= 49.3°. All specimens normally magnetized.

R 63	Eocene in age purple to whitish color limestone material approximately in 4 meters thickness.	16 samples were drilled, 16 specimens were demagnetized via AF and TH	4 specimens TH, 6 specimens AF, 6 specimens were measured combine	Initial intensities between 200- 4300 $\mu\text{A/m}$. Isolated ranges about 80°C-580°C or between 150°C plus 20 mT and 80 mT	All specimens interpreted without GC	ChRM (N=14) result is D=95.4°, I= 65.1°. All specimens normally magnetized.
R 66	Oligocene in age red to yellow color sandstone-conglomerate and mudstone material approximately in 15 meters thickness.	15 samples were drilled, 15 specimens were demagnetized via AF and TH	4 specimens TH, 5 specimens AF, 6 specimens were measured combine	Initial intensities between 4000- 82000 $\mu\text{A/m}$. Isolated ranges about 180°C-450°C or between 150°C plus 12 mT and 50 mT	12 specimens GC and 1 specimens selected as a Set Point	ChRM (N=13) result is D=202.5°, I= -61.5°. There are 9 specimens reversely magnetized.
R 70	Paleocene in age green to yellow color sandstone-claystone and mudstone material approximately in 6 meters thickness.	21 samples were drilled, 15 specimens were demagnetized via AF and TH	4 specimens TH, 5 specimens AF, 6 specimens were measured combine	Initial intensities between 30000- 60000 $\mu\text{A/m}$. Isolated ranges about 450°C-650°C or between 150°C plus 40 mT and 90 mT	All specimens interpreted without GC	ChRM (N=15) result is D=72.4°, I= 49.3°. All specimens normally magnetized.
R 71	Up Miocene-Pliocene in age red to yellow color mudstone material approximately in 5 meters thickness.	18 samples were drilled, 17 specimens were demagnetized via AF and TH	4 specimens TH, 7 specimens AF, 6 specimens were measured combine	Initial intensities between 6000- 18000 $\mu\text{A/m}$. Isolated ranges about 200°C-650°C or between 150°C plus 40 mT and 90 mT	All specimens interpreted without GC	ChRM (N=15) result is D=8°, I= 63.7°. There are 1 specimen reversely magnetized.

R 72	Oligocene in age red to yellow color sandstone-mudstone material approximately in 4 meters thickness.	21 samples were drilled, 20 specimens were demagnetized via AF and TH	4 specimens TH, 8 specimens AF, 6 specimens were measured combine	Initial intensities between 160- 650 $\mu\text{A/m}$. Isolated ranges about 80°C-380°C or between 150°C plus 6 mT and 45 mT	18 specimens GC and 1 specimens selected as a Set Point	ChRM (N=18) result is D=280°, I= -66.5°. All specimens reversely magnetized.
R 79	Low-Middle Eocene in age yellowish to green color sandstone-claystone material approximately in 7 meters thickness. Yamak formation?	17 samples were drilled, 17 specimens were demagnetized via AF and TH	4 specimens TH, 7 specimens AF, 6 specimens were measured combine	Initial intensities between 400- 1300 $\mu\text{A/m}$. Isolated ranges about 180°C-380°C or between 150°C plus 6 mT and 40 mT	13 specimens GC and 4 specimens selected as a Set Point	ChRM (N=17) result is D=36.6°, I= 63.3°. All specimens normally magnetized.
R 80	Low-Middle Eocene in age yellowish to green color sandstone-claystone material approximately in 4 meters thickness. Eskipolatli formation?	11 samples were drilled, 13 specimens were demagnetized via AF and TH	4 specimens TH, 3 specimens AF, 6 specimens were measured combine	Initial intensities between 200- 14500 $\mu\text{A/m}$. Isolated ranges about 80°C-500°C or between 150°C plus 6 mT and 60 mT	All specimens interpreted without GC	ChRM (N=13) result is D=264°, I= 44.4°. All specimens normally magnetized.
R 81	Low-Middle Eocene in age yellowish to green color sandstone-claystone material approximately in 4 meters thickness. Yamak formation?	14 samples were drilled, 13 specimens were demagnetized via AF and TH	4 specimens TH, 3 specimens AF, 6 specimens were measured combine	Initial intensities between 500- 1250 $\mu\text{A/m}$. Isolated ranges about 80°C-340°C or between 150°C plus 6 mT and 80 mT	All specimens interpreted without GC	ChRM (N=13) result is D=38°, I= 46.2°. All specimens normally magnetized.

R 82	Low-Middle Eocene in age yellowish to green color sandstone-claystone material approximately in 8 meters thickness. Yamak formation?	20 samples were drilled, 20 specimens were demagnetized via AF and TH	4 specimens TH, 10 specimens AF, 6 specimens were measured combine	Initial intensities between 1000- 30000 $\mu\text{A/m}$. Isolated ranges about 80°C-560°C or between 150°C plus 6 mT and 80 mT	All specimens interpreted without GC	ChRM (N=20) result is D=333.6°, I= 39.5°. All specimens normally magnetized.
R 84	Up Miocene-Pliocene in age white color tuff approximately in 11 meters thickness.	28 samples were drilled, 21 specimens were demagnetized via AF and TH	21 specimens were measured AF	Initial intensities between 80000- 350000 $\mu\text{A/m}$. Isolated ranges between 8 mT and 60 mT	All specimens interpreted without GC	ChRM (N=21) result is D=163.8°, I= -49.6°. All specimens reversely magnetized.
R 85	Low-Middle Eocene in age yellowish to green color sandstone material approximately in 16 meters thickness.	27 samples were drilled, 21 specimens were demagnetized via AF and TH	4 specimens TH, 11 specimens AF, 6 specimens were measured combine	Initial intensities between 500- 13500 $\mu\text{A/m}$. Isolated ranges about 150°C-420°C or between 150°C plus 8 mT and 80 mT	All specimens interpreted without GC	ChRM (N=20) result is D=326.7°, I= 62.6°. All specimens normally magnetized.
R 86	Low-Middle Eocene in age yellowish to green color sandstone material approximately in 5 meters thickness.	13 samples were drilled, 13 specimens were demagnetized via AF and TH	4 specimens TH, 3 specimens AF, 6 specimens were measured combine	Initial intensities between 500- 3500 $\mu\text{A/m}$. Isolated ranges about 150°C-420°C or between 150°C plus 6 mT and 27 mT	9 specimens GC and 3 specimens selected as a Set Point	ChRM (N=11) result is D=304.2°, I= 67.6°. All specimens normally magnetized.

RN1	Low-Middle Eocene in age yellowish to green color sandstone material approximately in 5 meters thickness. Eskipolatli formation.	19 samples were drilled, 21 specimens were demagnetized via AF and TH	4 specimens TH, 11 specimens AF, 6 specimens were measured combine	Initial intensities between 100- 3500 μ A/m. Isolated ranges about?	no set points and no GC	No result, because of remagnetization or big overprint over
RN4	Low-Middle Eocene in age yellowish to green color sandstone material approximately in 15 meters thickness. Yamak formation.	18 samples were drilled, 21 specimens were demagnetized via AF and TH	4 specimens TH, 11 specimens AF, 6 specimens were measured combine	Initial intensities between 6000- 25000 μ A/m. Isolated ranges about 450°C-580°C or between 150°C plus 10 mT and 35 mT	19 specimens GC and 2 specimens selected as a Set Point	ChRM (N=21) result is D=31.4°, I= 34.7°. There are 7 specimens reversely magnetized.
RN5	Low-Middle Eocene in age reddish to green color sandstone material approximately in 5 meters thickness. Yamak formation.	16 samples were drilled, 21 specimens were demagnetized via AF and TH	4 specimens TH, 11 specimens AF, 6 specimens were measured combine	Initial intensities between 15000- 33000 μ A/m. Isolated ranges about 180°C-580°C or between 150°C plus 10 mT and 80 mT	All specimens interpreted without GC	ChRM (N=20) result is D=1.1°, I= 48.5°. All specimens normally magnetized.
RN7	Low-Middle Eocene in age yellowish to white color fossiliferous limestone-marl material approximately in 8 meters thickness.	19 samples were drilled, 21 specimens were demagnetized via AF and TH	4 specimens TH, 11 specimens AF, 6 specimens were measured combine	Initial intensities between 20-40 μ A/m. Isolated ranges about 100°C-350°C or between 150°C plus 16 mT and 50 mT	13 specimens GC and 8 specimens selected as a Set Point	ChRM (N=21) result is D=319.9°, I=44.0°. All specimens normally magnetized.
RN8	Lower-Mid. Miocene in age and purple to white color marl	13 samples were drilled, 11	4 specimens TH, 7	Initial intensities between 10000- 40000 μ A/m. Isolated	no remnant	Lightning.

	approximately in 12 meters thickness.	specimens were demagnetized via AF and TH	specimens AF	ranges?		
SEC1	Low-Middle Eocene in age yellowish to green color sandstone-clay material approximately in 564 meters thickness. Eskipolatli formation.	610 samples were drilled, 400 specimens were demagnetized via AF and TH	200 specimens TH, 200 specimens AF were measured	Initial intensities between ~350-34000 μ A/m. Isolated ranges about 350°C - 580°C	All specimens interpreted without GC	ChRM (N=79) result is D=120.4°, I= -39.2°. There are normal and reverse magnetization
SEC5	Low-Middle Eocene in age yellowish to green color sandstone-clay material approximately in 564 meters thickness. Eskipolatli formation.	394 samples were drilled, 197 specimen with AF and 146 were demagnetized wit TH	46 specimens with TH were interpreted	Initial intensities between ~350-32000 μ A/m. Isolated ranges about 350°C - 550°C	All specimens interpreted without GC	ChRM (N=46) result is D=52.9°, I= 53.1°. There are normal and reverse magnetization
S 1	Lower-Mid. Miocene in age and bluish to white color, fine grain marl, mixed clay and sandstone material approximately in 7 meters thickness.	24 samples were drilled, 20 specimens were demagnetized via AF and TH	4 specimens TH, 10 specimens AF, 6 specimens were combine measured	Initial intensities between ~120-1600 μ A/m. Isolated ranges about 100°C - 310°C or between 150°C plus 4 mT and 70mT	All specimens interpreted without GC	ChRM (N=46) result is D=332.6°, I= 45°. All specimens normally magnetized.
S 2	Lower-Mid. Miocene in age and bluish to white color, fine grain muddy loose material	3 samples were drilled, 0 specimens were	-	-	-	-

	approximately in 3 meters thickness.	demagnetized					
S 3	Lower-Mid. Miocene in age and bluish to white color, fine grain marl, mixed clay and sandstone material approximately in 3 meters thickness.	27 samples were drilled, 20 specimens were demagnetized via AF and TH	4 specimens TH, 11 specimens AF, 5 specimens were measured combine	Initial intensity ranges between -2000-4200 $\mu\text{A/m}$. Isolated intensities about 180°C -540°C or between 150°C plus 15 mT and 80 mT	All specimens interpreted without GC	ChRM (N=19) result is D=358.3°, I= 75°. All specimens normally magnetized.	
S 4	Up. Miocene-Pliocene in age and reddish to blue color, fine grain marl, mixed clay and sandstone material approximately in 3 meters thickness.	24 samples were drilled, 14 specimens were demagnetized via AF and TH	4 specimens TH, 4 specimens AF, 6 specimens were measured combine	Initial intensity ranges between -100-300 $\mu\text{A/m}$. Isolated intensities about 80°C -290°C or between 150°C plus 4 mT and 50 mT	All specimens interpreted without GC	ChRM (N=12) result is D=322.9°, I= 33°. There are two reversely magnetized specimens.	
S 5	Lower-Mid. Miocene in age and bluish to white color, fine grain marl, claystone material approximately in 6 meters thickness.	28 samples were drilled, 20 specimens were demagnetized via AF and TH	4 specimens TH, 9 specimens AF, 7 specimens were measured combine	Initial intensity ranges between -240-810 $\mu\text{A/m}$. Isolated intensities about 180°C -250°C or between 150°C plus 30 mT and 80 mT	All specimens interpreted without GC	ChRM (N=14) result is D=151.6°, I=-40.1°. All specimens reversely magnetized.	
S 6	Lower-Mid. Miocene in age and bluish to green color, fine grain marl, shale material approximately in 3 meters	39 samples were drilled, 20 specimens were demagnetized via	4 specimens TH, 10 specimens AF, 6 specimens were	Initial intensity ranges between -200-1400 $\mu\text{A/m}$. Isolated intensities about 80°C -230°C or between	All specimens interpreted without GC	ChRM (N=20) result is D=303.3°, I=41.5°. All specimens normally	

	thickness.	AF and TH	measured combine	150°C plus 30 mT and 70 mT		magnetized.
S 7	Eocene in age and dark brown color, fine grain andesite, approximately in 11 meters thickness.	23 samples were drilled, 20 specimens were demagnetized via AF and TH	4 specimens TH, 10 specimens AF, 6 specimens were measured combine	Initial intensity ranges between -2000-12000 μ A/m. Isolated intensities about 350°C -280°C or between 150°C plus 40 mT and 90 mT	All specimens interpreted without GC	ChRM (N=16) result is D=206.3°, I=-23.2°. All specimens normally magnetized.
S 8	Up. Eocene-Low. Miocene in age and reddish to blue color, fine grain marl, mixed clay and sandstone material approximately in 4 meters thickness.	27 samples were drilled, 20 specimens were demagnetized via AF and TH	4 specimens TH, 10 specimens AF, 6 specimens were measured combine	Initial intensity ranges between -1000-2200 μ A/m. Isolated intensities about 80°C -200°C or between 150°C plus 15 mT and 50 mT	All specimens interpreted without GC	ChRM (N=10) result is D=198.4°, I= -37.2°. There are six reversely magnetized specimens.
S 9	Up. Eocene-Low. Miocene in age and reddish to blue color, fine grain marl, mixed clay and sandstone material approximately in 4 meters thickness.	24 samples were drilled, 20 specimens were demagnetized via AF and TH	4 specimens TH, 10 specimens AF, 6 specimens were measured combine	Initial intensities between -50-120 μ A/m. Isolated ranges about 80°C -200°C or between 150°C plus 15 mT and 50 mT	All specimens interpreted without GC	ChRM (N=17) result is D=60.8°, I= 55.5°. All specimens normally magnetized.
SF 1	Pliocene in age and white color, fine grain marl, mixed clay material approximately in 8	20 samples were drilled, 20 specimens were demagnetized via	5 specimens TH, 15 specimens were measured AF	Initial intensities between -50-1200 μ A/m. Isolated ranges about 20 -	5 specimens GC and 9 specimens selected as a Set	ChRM (N=14) result is D=5.9°, I= 42.1°. All specimens normally

	meters in thickness.	AF and TH		310°C or 4 mT and 45mT	Point	magnetized.
SF 2	Miocene in age and white color, fine grain marls/mudstones approximately in 5 meters in thickness.	20 samples were drilled, 20 specimens were demagnetized via AF and TH	5 specimens TH,15 specimens were measured AF	Initial intensities between -50-1200 μ A/m. Isolated ranges about 20 - 310°C or 4 mT and 45mT	6 specimens GC and 10 specimens selected as a Set Point	ChRM (N=16) result is D=27.4°, I= 48.9°. All specimens normally magnetized.
SF 3	Pliocene in age and white color, fine grain marl, mixed clay material approximately in 6 meters in thickness.	20 samples were drilled, 20 specimens were demagnetized via AF and TH	5 specimens TH,15 specimens were measured AF	Initial intensity ranges between -50-4200 μ A/m. Isolated ranges about 150 - 550°C or 12 mT and 50 mT	All specimens interpreted without GC	ChRM (N=10) result is D=2.7°, I= 59.1°. All specimens normally magnetized.
SF 4	Pliocene in age and white color, fine grain marl, mixed clay material approximately in 9 meters in thickness.	16 samples were drilled, 16 specimens were demagnetized via AF and TH	5 specimens TH,11 specimens were measured AF	Initial intensity ranges between -7500-103000 μ A/m. Isolated intensities about 80°C -290°C or between 150°C plus 4 mT and 50 mT	6 specimens GC and 10 specimens selected as a Set Point	ChRM (N=12) result is D=35.5°, I= 35.3°. There are two reversely magnetized specimens.
SF 5	Miocene in age and white color, fine grain marls/mudstones approximately in 6 meters in	15 samples were drilled, 15 specimens were demagnetized via	5 specimens TH,10 specimens were measured AF	Initial intensity ranges between 17000-1200000 μ A/m. Isolated ranges about 410 -600°C or 25 mT and 60	2 specimens GC and 10 specimens selected as a Set	ChRM (N=12) result is scattered

	thickness.	AF and TH		mT	Point	
SF 6	Miocene in age and white color, fine grain marls/mudstones approximately in 8 meters in thickness.	16 samples were drilled, 16 specimens were demagnetized via AF and TH	5 specimens TH,11 specimens were measured AF	Initial intensity ranges between 5000-10400 μ A/m. Isolated ranges about 100 - 500°C or 12 mT and 45 mT	All specimens interpreted without GC	ChRM (N=20) result is $D=2.5^\circ$, $I=54.6^\circ$. All specimens normally magnetized.

CURRICULUM VITAE

PERSONAL INFORMATION

Surname, Name: Murat, Özkaptan

Nationality: Turkish (TC)

Date and Place of Birth: 09 March 1981, Sinop

Marital Status: Single

Phone: +90 505 585 18 88

Fax: +90 312 210 57 50

E-mail: muratozkaptan@gmail.com

EDUCATION

Degree	Institution	Graduation Year
MS	KTÜ Geophysical Engineering	2006
BS	KTÜ Geophysical Engineering	2002
High School	Gerze High School, Gerze-SİNOP	1998

WORK EXPERIENCE

Year	Place	Enrollment
2008-Present	METU Department of Geological Engineering	Research Assistant
2005-2007	KTÜ Department of Geophysical Engineering	Research Assistant
2005-2005	Çelebi Ground Handling	Ground Operator

FOREIGN LANGUAGES

Fluent English
