## **ABSTRACT**

### **DEVELOPMENT OF A DECISION SUPPORT SYSTEM FOR OPTIMAL INSTRUMENTATION OF CONCRETE FACED ROCKFILL DAMS**

Ari, Onur

Ph.D., Department of Civil Engineering

Supervisor: Prof. Dr. A. Melih Yanmaz

September 2016, 219 pages

In this study, an algorithm for optimal design of instrumentation systems for concrete faced rockfill dams was developed. The aim of this algorithm is to determine the number and the location of individual instruments for stress monitoring. It was intended to develop a user-friendly and flexible algorithm that would be applicable in reliable and economic design of instrumentation systems for concrete faced rockfill dams. The first developmental step was the generation of a model cross-section for a concrete faced rockfill dam. Possible loadings were applied to this model cross-section. With the execution of a number of analyses for various dam heights via computer-assisted finite element analyses, some stress contours were obtained. These stress contours of different dam heights were analysed to end up with a representative stress distribution model. Then the governing dimensionless equations were formed for obtaining the magnitudes and location of different stress zones as a function of dam height. These zones provided information about the general trend of the overstressed areas. By expansion of the analyses, an algorithm for proper location and number of such equipment was obtained. An optimization algorithm to be used for horizontal placement of sensors in one of the standard sections were developed and the results were analysed. A vertical placement algorithm based on error minimization was also

developed and two algorithms were combined. The final optimization scheme was demonstrated for a number of dams and the sensitivity of the algorithm was also analysed. It can be said that this optimization scheme provides a basis for the design of an instrumentation system for concrete faced rockfill dams considering both the economy and the effectiveness in terms of data quality of the instrumentation system.

## ÖZ

# ÖN YÜZÜ BETON KAPLI KAYA DOLGU BARAJLARIN İZLEME SİSTEMLERİNİN EN UYGUN TASARIMI İÇİN BİR ALGORİTMA GELİŞTİRİLMESİ

Arı, Onur

Doktora, İnşaat Mühendisliği Bölümü

Tez Yöneticisi: Prof. Dr. A. Melih Yanmaz

Eylül 2016, 219 sayfa

Bu çalışmada, ön yüzü beton kaplı kaya dolgu barajların izleme sistemlerinin optimum tasarımı için bir algoritma geliştirilmiştir. Bu algoritmanın amacı, bağımsız yük ölçerlerin sayısını ve yerlerini belirlemektir. Ön yüzü beton kaplı kaya dolgu barajların izleme sistemleri için kullanım kolay ve esnek bir algoritma geliştirilmesiyle bu sistemlerin tasarımlarının daha güvenilir ve ekonomik yapılabileceği öngörmektedir. İlk adımda, bilgisayar destekli sonlu elemanlar analizi için model kabul edilen ön yüzü beton kaplı kaya dolgu bir baraj kesiti geliştirilmiştir. Bu bağlamda, değişken yükseklikteki baraj kesitlerine olası yüklemeler uygulanmıştır. Bu analizlerin değişken baraj yüksekliklerine uygulanması sonucunda eş-yük eğrileri elde edilmiştir. Bu eş-yük eğrilerinin değişken baraj yükseklikleri ve yükleme koşullarına uygulanmasının sonucunda ise temsili bir yük dağılım modeli oluşturulmuştur. Böylece eş-yük eğrileri boyut ve büyülüklerini baraj yüksekliğine göre veren denklemler elde edilmiştir. Eş-yük eğrileri, baraj gövdesindeki aşırı yüklenmiş bölgelerin genel eğilimleri ile ilgili bilgiler vermiştir. Analizlerin genişletilmesi ile aygıtların gövde içindeki en uygun yerleri ve sayıları elde edilmiştir. Sensörlerin standart bir kesit içinde yatay doğrultuda yerleştirilmesi için bir optimizasyon algoritması geliştirilmiştir ve elde edilen sonuçlar değerlendirilmiştir. Dikey doğrultuda sensör yerleşimi için kullanılacak hata küçültme

tabanlı bir algoritma da geliştirilmiş ve bahsedilen iki algoritma birleştirilmiştir. Sonuçta elde edilen optimizasyon planı çeşitli baraj kesitlerinde denenmiş ve algoritmanın hassasiyeti de analiz edilmiştir. Bu optimizasyon planının ön yüzü beton kaplı kaya dolgu barajların izleme sistemlerinin hem ekonomik, hem de izleme sisteminden elde edilecek verinin kalitesini göz önünde bulunduran bir şekilde tasarlanması için temel oluşturacağı öngörülümektedir.

**Anahtar Kelimeler:** Baraj Güvenliği, Barajların İzlenmesi, Baraj Ölçüm Sistemleri, En Uygun Ölçüm Sistemi, Ön Yüzü Beton Kaplı Kaya Dolgu Baraj

*To My Mother and Father...*

## **ACKNOWLEDGEMENTS**

This study was supported by The Scientific and Technological Research Council of Turkey (TUBITAK) 2211-C Scholarship.

I would like to express my deepest gratitude to my supervisor Prof. Dr. A. Melih Yanmaz for his guidance, endless patience, and incredible support. Without his vision and ambition, this study would not have been possible.

Many thanks to my dissertation progress committee members Assoc. Prof. Dr. Nuri Merzi and Assoc. Prof. Dr. Ferhat Akgül for their valuable suggestions, comments and support.

It is with pleasure to express my genuine gratefulness to the Rt Hon. Kerem Ar and Dr. Musa McYılmaz for their exceptional brotherhood, encouragement, and endless support even sometimes from miles away.

Last but not the least, I would like to thank my mother and father for their endless love and patience.

## LIST OF SYMBOLS

$a$	parameter used in modelling of horizontal effective stress distribution
$B$	base width of the dam
$B_c$	crest width of the dam
$B^*$	width of a horizontal layer
$b$	parameter used in modelling of horizontal effective stress distribution
$C_c$	cost of cable
$C_E$	cost of equipment
$C_P$	cost of penalty
$C_s$	cost of sensor
$C_T$	total cost of instrumentation system
$c$	parameter used in modelling of horizontal effective stress distribution
$d$	parameter used in modelling of horizontal effective stress distribution
$e$	parameter used in modelling of horizontal effective stress distribution
$f$	parameter used in modelling of horizontal effective stress distribution
$g$	parameter used in modelling of horizontal effective stress distribution
$H_b$	base thickness of the dam
$H_f$	dam height from foundation level
$H_t$	dam height from thalweg level

$h^*$	height of a point on a horizontal projection from the foundation level
$N$	number of instruments on a horizontal projection
$N_T$	total number of instruments within a dam cross-section
$M$	number of horizontal projection on a dam cross-section
$P'_h$	projected horizontal effective force
$P'_v$	projected vertical effective force
$P'_v(N)$	modelled vertical effective force function
$P'_{vt}$	true vertical effective force function
$S_d$	horizontal run for 1 m-rise at downstream side slope
$S_u$	horizontal run for 1 m-rise at upstream side slope
$x$	horizontal distance of a point from (0, 0)
$x_f$	horizontal distance of the last point on a horizontal projection from (0, 0)
$x_s$	horizontal distance of the first point on a horizontal projection from (0, 0)
$y$	height of a point on a vertical projection from the foundation level
$\sigma'_h$	horizontal effective stress on a point
$\sigma'_v$	vertical effective stress on a point
$\sigma'_{vmax}$	maximum vertical effective stress on a layer
$\sigma'_{vmin}$	minimum vertical effective stress on a layer
$\gamma$	specific weight of water

## **CHAPTER 1**

### **INTRODUCTION**

#### **1.1 General**

Growing demand to energy and water leads to a great increase in dam construction activities. Dams may exhibit potential risk of failure depending on structural type, aging effects, and local site characteristics. In the case of collapse of a dam, valuable farm areas may be flooded, various types of private or public properties may be severely damaged and last but not the least, many fatalities may occur. In order to protect the people and the properties, it can be said that a dam must be as safe as possible. Although, the lessons learned from past events forced designers to develop sophisticated approaches, there still exists an unknown level of risk related with the dam body itself and the appurtenant structures. Due to the uncertain nature of hydro-meteorological data, foundation properties, material deficiencies, and constructional quality, every dam project imposes a potential risk, which can be reduced only if various sources of uncertainties are identified and handled in modelling (Yanmaz and Ari, 2011). This would result in economic savings.

#### **1.2 Statement of the Problem**

There is a growing tendency for constructing Concrete Faced Rockfill Dams (CFRDs) worldwide due to their apparent advantages regarding saving in construction duration and no-requirement to impermeable core. Similar to the case of other types of dams, an effective instrumentation system should be implemented to CFRDs to obtain information about the structural behaviour throughout the lifetime of these structures. The layouts of bodies of some existing CFDSs reported in the literature were examined according to the distribution of various types of instruments. However, no specific

guidelines regarding arrangement practices for instruments were found. Therefore, this gap in the literature is considered to be the triggering point of this study, which is carried out specifically for CFRDs.

This study attempts to find a logical answer to the questions that may arise during the design phase of a CFRD. The main question is related with the locations of the sensors to measure a structural health indicator of a dam. The secondary question would emerge quickly as well, which is related with the number of sensors within a structure. The aim is to provide a sound and logical decision support system which can provide the solution to the dam monitoring system designers considering the required amount of information from the sensor network with the lowest possible cost.

### **1.3 Scope of the Study**

In this study, an algorithm for optimal design of monitoring and instrumentation system for CFRDs was developed. The aim of this algorithm is to determine the number and the location of individual instruments for stress-strain monitoring throughout the dam body. This selection is greatly dependent on the evaluation of the structural behaviour of this type of dam. It is intended to develop a user-friendly and flexible algorithm that would be applicable in reliable and economic instrumentation system design of concrete faced rockfill dams.

The first developmental step was the generation of a model cross-section for a concrete faced rockfill dam with respect to stress contours. To this end, a particular loading was applied to a model cross-section of variable height. A realistic execution of the software depends mainly on the description of foundation material properties, contact details between the dam and foundation and concrete upstream facing, and the assumptions made. The software PLAXIS was used for this purpose throughout this study.

Chapter 2 provides brief information about CFRDs, such as history, advantages over other types of dams, and design principles. Chapter 3 gives brief information about the items that should be monitored in CFRDs and summarizes the sensor types to be used in monitoring systems of CFRDs. The scope of the study and the development of the model are explained in detail in Chapter 4. The algorithm outputs and the effects of seepage, earthquake loading, and the alternative placement of sensors are also discussed in Chapter 4. In Chapter 5, the comparison and verification of the algorithm outputs with the instrumentation of existing CFRDs are presented. Finally, the conclusions and recommendations for further studies are provided in Chapter 6.

## **CHAPTER 2**

### **CONCRETE FACED ROCKFILL DAMS**

#### **2.1 Brief Information about CFRDs**

A Concrete Faced Rockfill Dam (CFRD) is a kind of embankment dam having an impervious concrete slab on the upstream face of underlying rockfill body in order to achieve watertightness rather than employing an impervious clay core. The hydrostatic load of the reservoir improves the overall stability of the dam body. With the properly constructed upstream concrete facing, the fill materials and zones of a CFRD are not saturated which prevents the occurrence of the pore water pressure within the dam body. CFRDs are gaining popularity from day to day because of their benefits. That is why initiative type selection studies of dam projects include CFRD alternative as the recent trend. Their advantages are listed as relatively low construction costs compared to other types of dams, simplicity in embankment formation, general suitability to different natural and foundation conditions, and shorter construction period. Other key factors favouring selection of concrete faced rockfill dams are their better performance in humid climates and no dependency on impervious soil reserves (Özkuzukıran et al., 2006).

A list of CFRDs in Turkey under service or during planning and construction stages is given in Table 2.1 in which E is energy, MW is municipal water, and IW is irrigation water.

Table 2.1 Concrete faced rockfill dams in Turkey

<b>Dam</b>	<b>Province</b>	<b>River</b>	<b>Purpose</b>
Aladereçam	Gümüşhane	Karaovacık	E
Alaköprü	Mersin	Dragon	E + MW

In spite of the aforementioned advantages of CFRDs, design of the impervious upstream facing requires great attention. Since the design of CFRDs is generally based on the expert judgment and engineering experience (Cooke, 1984), various properties of this face slab should be studied extensively with utmost care. A typical cross-section of a CFRD is given in Figure 2.1.

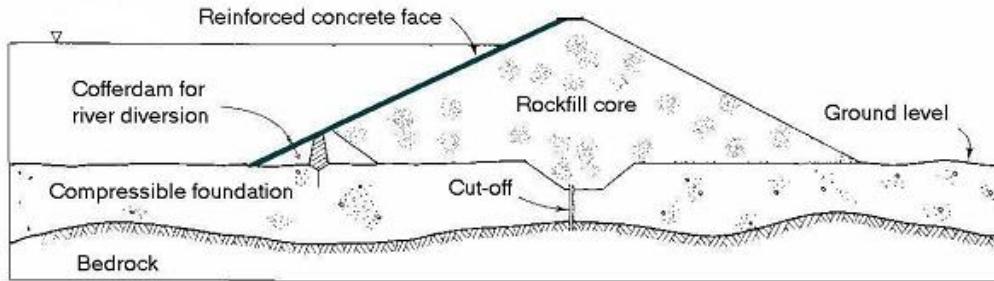

Figure 2.1 A typical CFRD cross-section (Chau Chin, 2004)

## 2.2 History of CFRDs

CFRD application originated from gold mining region of Sierra Nevada in California by 1850s. Gold miners developed the construction technique of dumped rockfill dams in order to provide cooling water for their drilling equipment. In early times, these dumped rockfill dams had been waterproofed by wooden upstream facings, which were by time replaced by concrete facing (ICOLD, 1989). The first dam which can be considered as a CFRD is Chatsworth Dam which was constructed in California in 1895.

The second development period of CFRD is named as the transition period (ICOLD, 2005). During this period, a number of problems were faced by the engineers. Three most observed problems during that era were the excessive settlement of the relatively high CFRDs, insufficient compaction, and serious seepage from the concrete face slab and plinth. New Exchequer Dam in California completed in 1965 is accepted as the last example of the CFRDs constructed during the transition period (Ergeneman, 2012).

The modern era of the CFRDs was initiated with the advancement of vibratory roller compactors. Better compaction with more efficient controlling of water content of the

fill material leaded to an obvious increase in dam performance. The developments in compaction techniques and the zoning of CFRDs have greatly reduced the settlements of dam body and thus helped to the concrete face slab to stay intact and prevented water seepage.

As a summary, starting from the wooden-face dumped rockfill dams built during the California Gold Rush, development and application of CFRDs was limited up to 1960's (Cooke, 1984). This was due to the limitation of machinery and materials. Starting from 1970's many CFRDs have been designed and constructed (Sherard and Cooke, 1987) due to the economic and technical advantages. The development of material, construction techniques and software analysis possibilities accelerated. Shuibuya Dam in China, passed the 200 m limit and is the highest concrete faced rockfill dam in the world with 233 m height (Özkuzukiran, 2005).

## **2.3 Characteristics of CFRDs**

In design-wise approach, CFRDs do not require any specific site and foundation conditions different from the impervious core rockfill dams (Sherard and Cooke, 1987). However, some components of CFRDs are exclusive to this type of dams and provide both watertightness and stability.

### **2.3.1 Plinth**

A plinth is an important part of a CFRD, located below the upstream concrete facing and foundation. It acts as a transition between the upstream face slab and the foundation which houses some filter materials. Its main role is to prevent foundation level seepage. Copper and rubber waterstops provide the watertightness and continue to provide it up to a predefined level of differential movement of plinth and concrete slab (Korkmaz, 2009). A plinth is also anchored to the foundation rock by the grouting

application. The grouting does not only fix the base of plinth to the ground, but also reduces the seepage beneath it. A typical plinth application is shown in Figure 2.2.

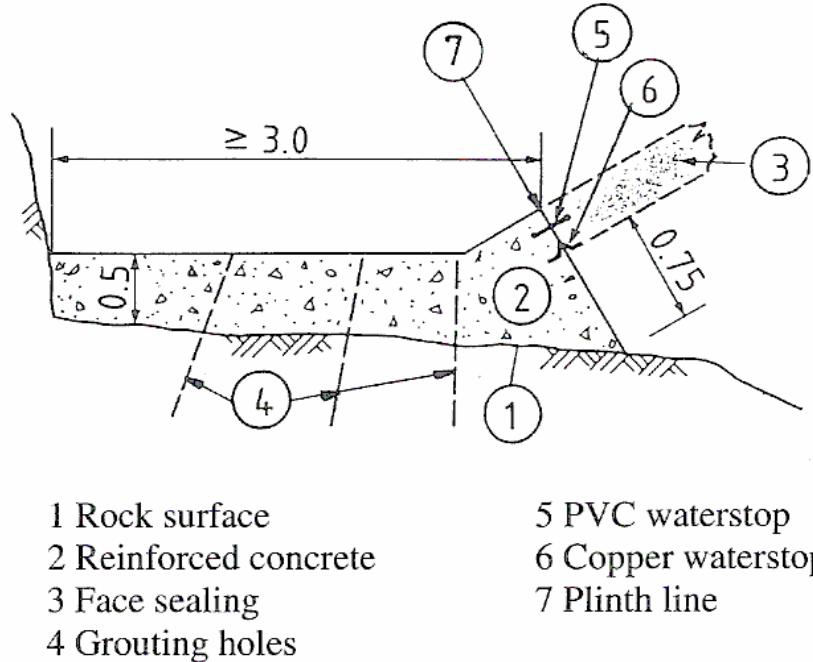

Figure 2.2 A typical plinth cross-section (ICOLD, 2005)

The dimensioning of the plinth has a significant effect on the stability. If the plinth has excessive height, a number of problems might be observed, such as loss of stability under full reservoir loads. ICOLD (1989) recommends to conduct sliding and overturning analyses. As a general rule of thumb, high plinths should be avoided in order to reduce the chance of seepage due to the excessive movements observed at plinth. The thickness of the plinth can be determined from Ergeneman (2012):

$$T = 0.3 + 0.003H_t \quad (2.1)$$

where,  $T$  is the thickness of the plinth in meters and the  $H_t$  is the height of the dam from thalweg in meters.

### 2.3.2 Face Slab

The face slab is the primary element of the CFRDs. It provides watertightness by blocking the water to seep through the dam body. Since no other element is placed inside the dam body, the design of the face slab requires great attention. Face slab can be considered as reinforced concrete plate which is supported by the fill material and is normally under compression (ICOLD, 2005). In Figure 2.3, construction of the upstream concrete face slab of Shuibuya Dam is presented.

Figure 2.3 Concrete face slab of Shuibuya Dam (Materon, 2013)

Although face slabs are considered under compression, the settlement of the dam body might create moment because of the loss of the support of the fill material. In order to reduce the effect of this problem, face slabs are reinforced. Face slabs are constructed in predetermined panel widths in order to reduce the effect of shrinkage during construction (ICOLD, 2005). In general, panel widths are chosen between 12 m and 18 m. Two successive face slab panels are equipped with waterstops in order to ensure the watertightness. Horizontal and vertical waterstops of the face slab of Kavşak Bendi Dam are presented in Figure 2.4.

Figure 2.4 Close-up view of the face slab of Kavşak Bendi Dam

The cracks on the face slab can be divided into three categories as cracks caused by the shrinkage of the concrete (Type-A), cracks caused by the settlement of the supporting fill material (Type-B), and cracks caused by the differential settlement of the dam body (Type-C) (Mori, 1999).

The Type-C cracks are the most common type of cracks. According to Marulanda and Pinto (2000), these cracks are related with the unexpected deformation of the fill body. The Type-C cracks of the face slab of Xingo Dam were as wide as 15 mm and located to the close vicinity of the left abutment (Souza et al., 1999). Those cracks were then filled with fine silt and sand (ICOLD, 2005). The cause of Type-C face slab cracking at Ita Dam was the use of less dense supporting material at distances away from the perimeter joint (Pinto, 2001).

Although small cracks can be filled by fine silt, sand, or fly ash, the cracks which are wider than 30 mm requires a different solution. Wu et al. (2000) recommends to treat wider cracks with a fly ash and a grouting mixture of cement and sand.

The concrete mix design of the face slab requires great attention. The concrete mix should be durable throughout the lifetime of the structure and help to minimize the shrinkage during curing period (ICOLD, 2005). Limiting the water content of the concrete mix will help to obtain a durable concrete (Jiang and Zhao, 2000). Durability of the concrete against freezing and thawing can be achieved by air entrainment. Jiang and Zhao (2000) recommends that the entrained air should be between 4 and 7 percent.

### **2.3.3 Perimeter Joints**

Perimeter joints are the main joints which are placed between the face slab and the plinth. The function of the perimeter joint is to allow the relative movements between the face slab and the plinth to some degree while maintaining the watertightness under various loading cases and reservoir water levels (ICOLD, 2005).

A perimeter joint consists of a number of elastic seals and filler materials to support the seals. A detailed cross-section of the perimeter joint of Salvajina Dam is presented in Figure 2.2.

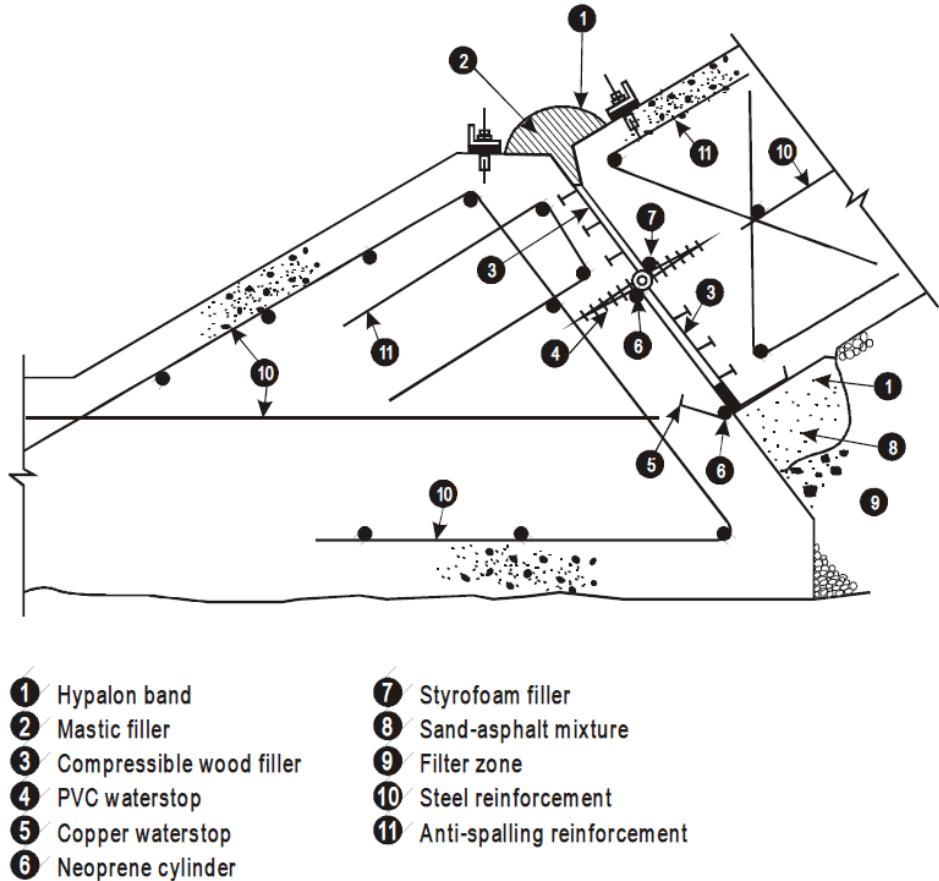

Figure 2.5 Perimeter joint detail of Salvajina Dam (ICOLD, 1989)

The development of the perimeter joints of CFRDs were started with Cethana Dam (Australia). The perimeter joint of Cethana Dam was designed with two subsequent waterstops. After five years of operation, the leakage reduced to 10 litres per second (Pinto and Mori, 1988). The attempts of reducing the waterstops of perimeter joints from two to one led to a drastic increase in the leakage rates of Alto Anchicaya Dam. In order to cope with this problem, mastic joint sealant was applied to the Alto Anchicaya Dam (ICOLD, 2005). Lessons learned from Alto Anchicaya Dam led to the development of three-layer perimeter joints.

### 2.3.4 Body Zoning

The body fill of a CFRD comprises many zones. Some of these zones act as a filter and bumper material between face slab, whereas the others support the load (ICOLD, 2005). General zoning and the material types of the zones are provided in Figure 2.6.

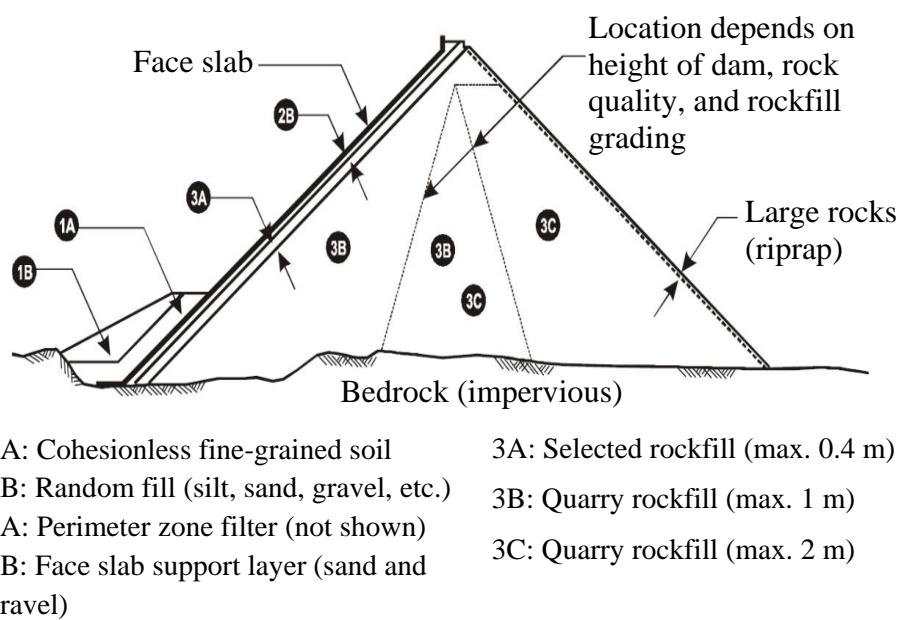

Figure 2.6 CFRD Zoning (ICOLD, 1994)

The 1A zone consists of fine sand, cohesionless silt, or fly-ash and the maximum particle size in this zone is 150 mm. The purpose of the 1A zone is to wash through the possible cracking on the face slab and clog the filter materials beneath the face slab. The 1B zone protects the 1A zone and is made of random fill of silt, sand, and gravel.

The 2A and 2B zones are also called as protective zones. The 2A zone acts as a filter for 1A zone material if any problem arises at perimeter zones. The 2B zone thickness

is between 2 to 4 m and supports the face slab with a low permeability. The 2B zone should be protected with utmost care during construction either by shotcrete application or concrete curbs (ICOLD, 2005).

The 3A zone is a transition zone which prevents the 2B zone to be washed away to 3B zone material. Zones 3B and 3C are the main rockfill zones of the dam body, whereas 3D zone is also called the riprap zone which protects the downstream face of the dam from environmental erosion.

Zones at the mid-axis of Kürtün Dam and Nam Ngum 2 Dam are presented in Figure 2.7 and Figure 2.8, respectively. It can be noticed that these material zones and grading changes in different dams, because the CFRD designs are mainly empirical and rely on the past experiences and expert judgements.

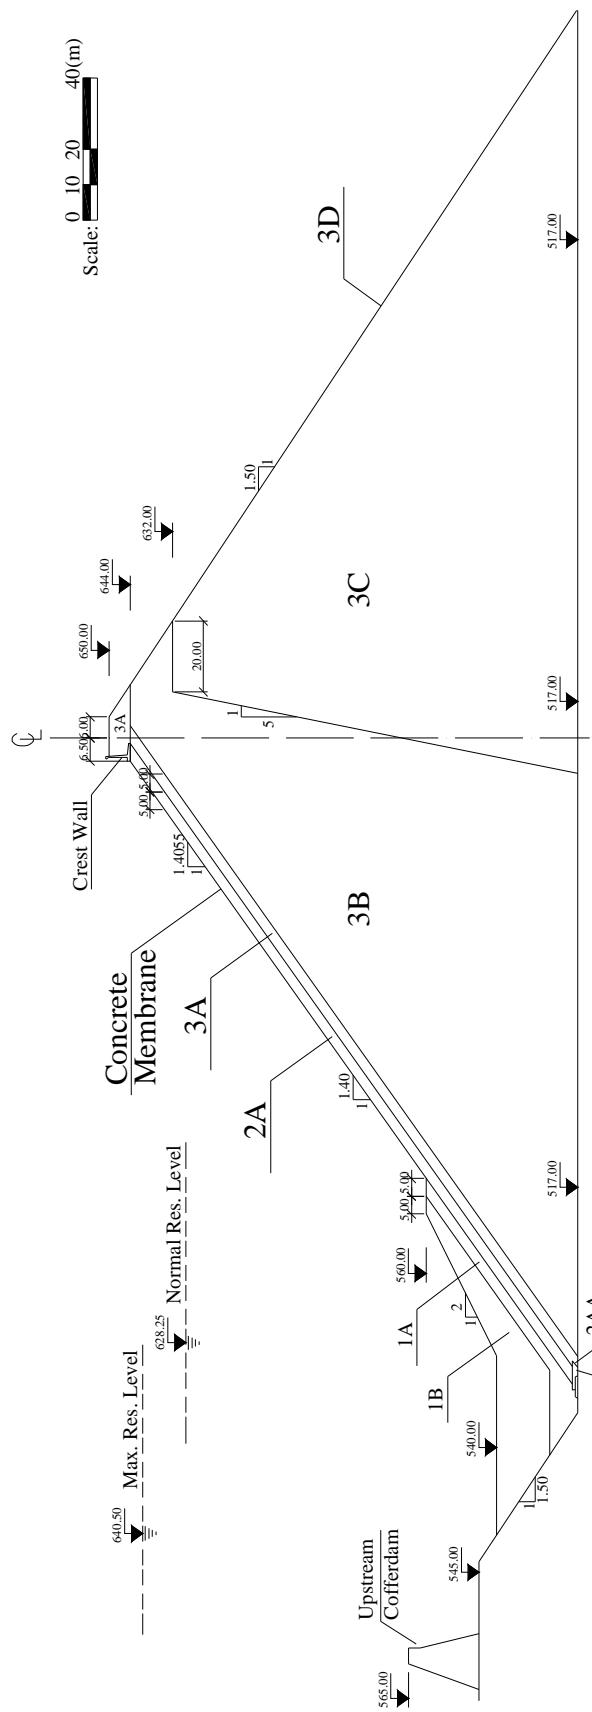

Figure 2.7 Zoning of Kürtün Dam (Özkuzukiran, 2005)

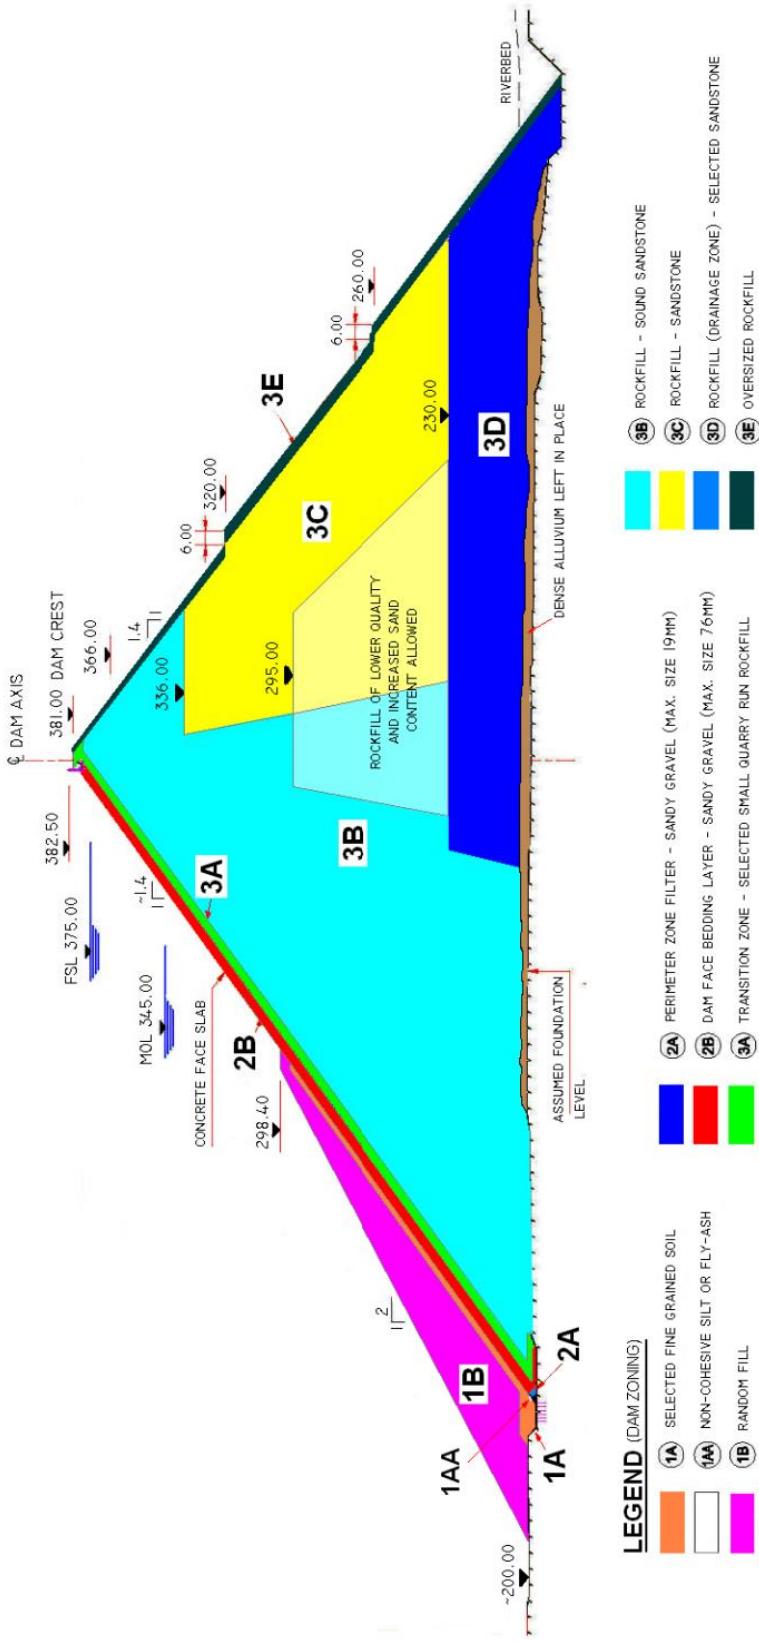

Figure 2.8 Zoning of Nam Ngum 2 Dam (Straubhaar et al., 2009)

## 2.4 CFRD Design Principles

Design of CFRDs comprises a number of essential analyses (ICOLD, 2005), such as:

- Static stability analysis
- Dynamic stability analysis
- Prediction of the settlement and the face slab deformation
- Prediction of the leakage.

Static stability analysis starts with the determination of the properties of the fill materials available in close vicinity. Since a dam construction requires vast amount of material, most of the time it would not be feasible to transport the fill material with desired properties. In the light of the material properties, the designer can, therefore, conduct slope stability analysis and determine the dimensions of the dam body and the side slopes.

Dynamic analysis would provide the anticipated behaviour of the dam during an earthquake and should be conducted if the dam site is susceptible to high seismicity. Although the rockfill dams are generally considered as safe structures against earthquakes, dynamic analysis provides an estimate of a possible crest settlement of the dam under the loading of a severe earthquake. According to ICOLD (2005), CFRDs should be designed by defensive design concept which dictates a sufficient freeboard to compensate a possible crest settlement after an earthquake. A number of widely used methods can be used to determine the crest settlement, such as Makdisi and Seed Method (Makdisi and Seed, 1977) and Bureau's Method (Bureau, 1997).

Settlements immediately after the construction lead to a decrease in freeboard which might increase the risk of overtopping. Settlements can be simply predicted with the

modulus of the elasticity of the rockfill material. However, the rockfill material is not perfectly elastic and Mohr-Coulomb material models might not work well. Some empirical approaches, such as the decision support system of Pinto and Marques (1998) can be used to predict the face slab deformation easily. However, with the advancement in finite element method and increased computing power, complex models, such as hardening soil models would provide more successful results.

Leakage performance of a CFRD is considered as the key parameter in determination of the success of the design. Although the leakage can be estimated with usual flow through porous medium concept, more detailed methods also take the effect of the discontinuities within the foundation and the dam body into account (Giesecke et al., 1991).

As a summary, CFRD design comprises of modelling of a vast number of variables. Before the advancement of computer-assisted design and analyses, some expert systems were developed by researchers. As a result of this, the CFRD designs were dependent on the expert opinions and judgements. The designs were developed with the lessons learned from the past experiences. However, the rapid rise of the computing power in the last few decades helped designers to introduce the effect of more variables to the problem.

Although the design procedures have evolved with the powerful computers and advanced software packages, the performance of the contemporary design applications still needs to be verified. With the advancement in technology, extremely sensitive and accurate sensors are available nowadays. These sensors not only validate the design, but also provide essential support for structural health monitoring. The next chapter gives detailed information about the purpose and the types of the sensors which are now accepted as vital for monitoring of the CFRDs.

## **CHAPTER 3**

### **MONITORING SYSTEMS OF CONCRETE FACED ROCKFILL DAMS**

#### **3.1 Items to be Monitored at CFRDs**

##### **3.1.1 Introductory Remarks**

CFRDs are prone to overtopping, sliding, seepage induced failures, excessive settlement, and slab cracking. Therefore, it is possible to assess life-long behaviour of CFRDs with the proper instrumentation system which is designed to capture, log, and process the vital structural health indicators of the dam.

##### **3.1.2 Seepage**

CFRDs are seepage-critical structures. In design phase, the upstream concrete facing is assumed to be fully watertight during the lifetime of the structure. However, even a small settlement or movement could lead to crack formation or joint openings on the upstream facing. With the absence of an impervious core, the seepage rate would then increase rapidly.

Anthiniac et al. (2002) state that every CFRD experiences some degree of leakage and the general trend among dam owners is to accept that increased leakage. It is also stated that this inevitable leakage would not cause a major safety concern because of the leakage-proof nature of the design and the materials. However, ICOLD (2005) stresses out that if a CFRD is built according to the state-of-the-art methods and meticulous workmanship, the leakage rates may be as low as 1 lt/sec.

The change in the hydrostatic water pressure within the dam body can provide information about the possible leakage from the face slab or perimeter joint. So it is beneficial to measure the hydrostatic water pressure within the dam body and at the foundation of the dam.

Measurement of the rate and the turbidity of the seepage flow will also provide valuable information about the change of the leakage with respect to reservoir level. Turbidity measurement would provide clues about the location of the initiation of the leakage.

### **3.1.3 Settlement, Deformation, and Movement**

Overtopping is a general weak point of embankment dams. CFRDs have a sound upstream facing but the downstream slope is generally unprotected as other types of embankment dams. Settlement of the dam body is one of the causes of overtopping, which may lead to a reduction in the freeboard (FERC, 1999).

Saturation of either foundation or embankment body will result in excessive settlement, which further impacts the concrete facing. Since upstream concrete face slab is an important integral part of the CFRDs, the condition of the face slab should be monitored periodically by means of joint opening and alignment monitoring.

Deformation of the structural elements provides vital information about the behaviour of the dam. Monitoring of the deformation also provides information about the internal stress changes within the dam body. Overall geometry changes which are measured from the outside of the dam would provide evidence about the differential movement of the dam foundation.

### 3.2 Types of Sensors

The basic instrumentation concept of CFRDs with the instruments and their purposes are summarized in Table 3.1.

Table 3.1 Instruments of CFRD (Moll and Straubhaar, 2011)

Instrument	Measured Parameter
3D Joint Meters	Movement of concrete face slab joints and perimeter joint
2D Joint Meters	Movement of concrete face slab joints
1D Joint Meters	Movement of concrete face slab joints
Inclinometers and Tiltmeters	Deflection of concrete face slab
Rebar Strain Gauges	Strain in concrete face slab
Concrete Strain Gauges	Strain in concrete face slab
No-Stress Strain Gauges	Reference strain in concrete
Embankment Extensometers	Transverse movement of the dam body
Settlement Cells	Settlement of the dam body
Surface Monuments	Movement of the surface
Strong Motion Accelerometers	Earthquake acceleration
Total Pressure Cells	Total pressure at dam body and foundation
Piezometers	Water pressure in dam / dam foundation and seepage
Seepage Measuring Weir	Seepage through the dam body and abutments

### 3.2.1 Total Pressure Cells

Total pressure cells have been used in dams since late 1950s and were appreciated in terms of their reliability over five years and consistent performance by Thomas and Ward (1969). Total pressure cells measure the changes of direct (effective) pressure acting over them. They are made of two steel plates firmly fixed each other from the edges to form a pad and is filled with an incompressible fluid (Ari, 2008). One end of the total pressure cell is equipped with a pressure transducer which measures the change in the pressure acting on the cell, and thus the oil. Some pressure cells are also equipped with thermistors for the determination of temperature in close vicinity of the sensor.

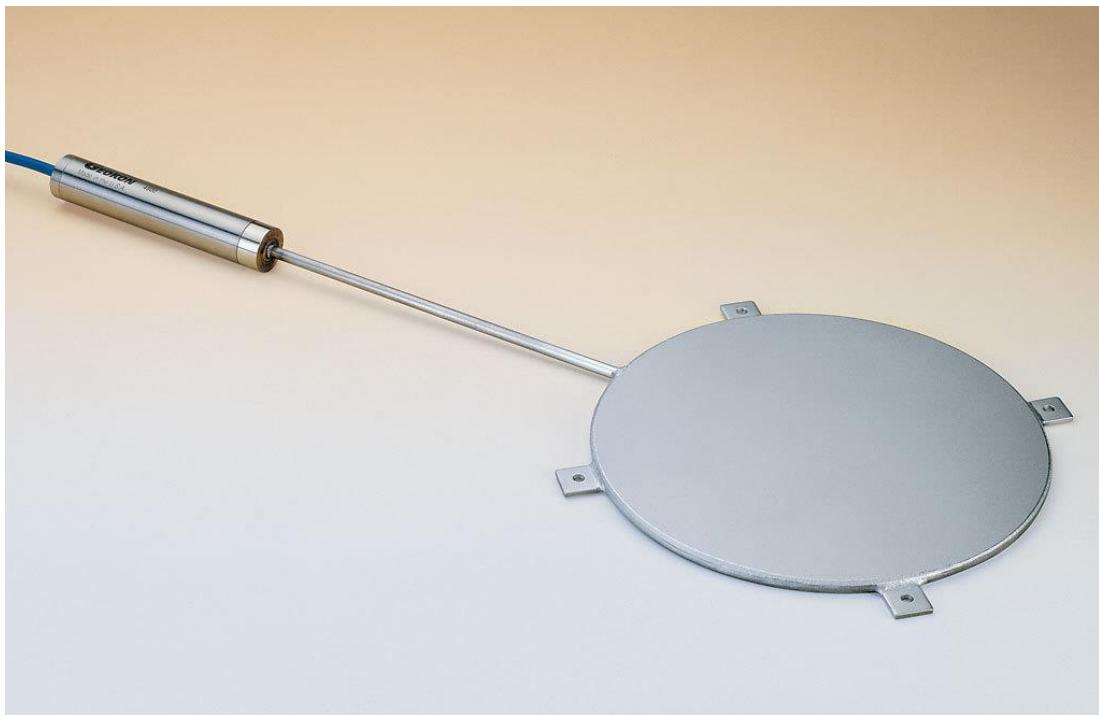

Figure 3.1 Standard type total pressure cell (Geokon, 2016-a)

Total pressure cells can be located to any place within dam body and foundation where the stress variations are of interest (Szostak-Chrzanowski and Massiéra, 2006). Their design varies according to the material types of which they are intended to stay in

contact. Standard total pressure cells are used for the measurement of the pressure within embankments (Figure 3.1). Pressure cells with a rigid back side are named as contact type total pressure cells and they are used to measure the pressure at the contact area of concrete (Figure 3.2).

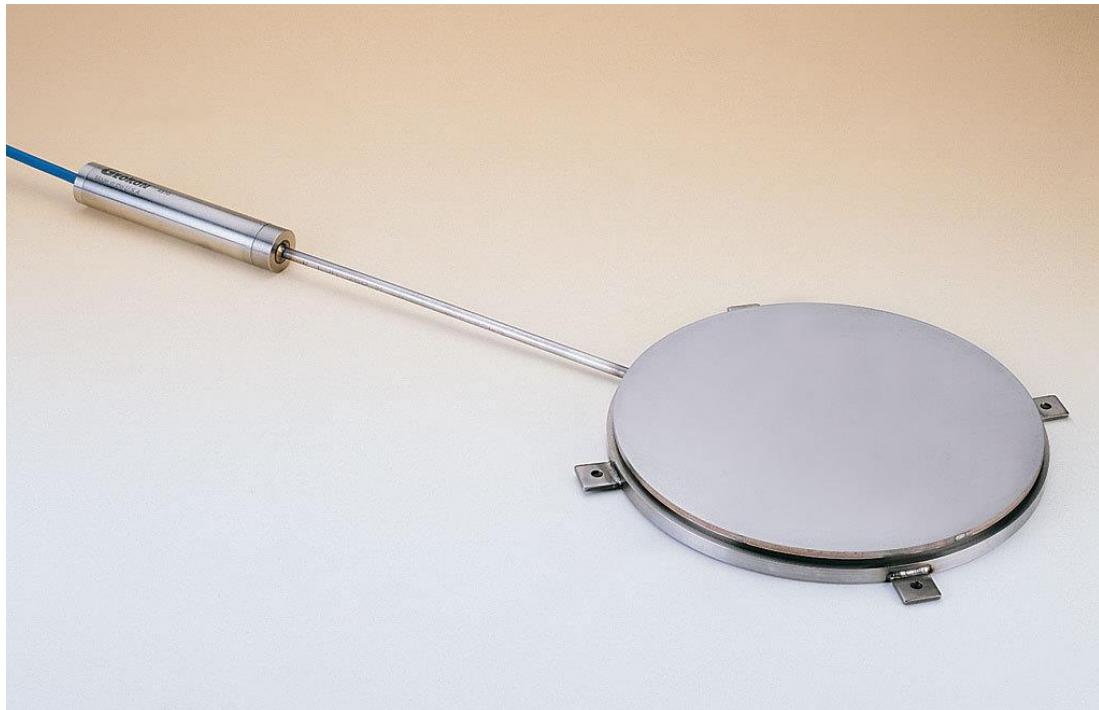

Figure 3.2 Contact type total pressure cell (Geokon, 2016-b)

### 3.2.2 Strain Meters

Strain meters are used to monitor the strain in one degree; although they can be mounted in a group for measuring the strains in more than one axis. They can be used to monitor the behaviour of the stress changes as well. Strain meters are used to monitor the stress and strain on the reinforcement bars used in the face slab (Yanmaz and Ari, 2008).

Embedment strain meters are embedded into a freshly poured concrete of piles, columns, beams, or face slabs in CFRDs. They measure the strain changes within the concrete. A typical embedment strain meter is presented in Figure 3.3.

Figure 3.3 Embedment strain meter (Geosense, 2013)

Strain meters are also used for determination of the strain on the reinforcement bars or steel elements. Weldable surface-mount strain meters are suitable for monitoring the steel structural elements, whereas the spot weldable strain meters are used to measure the strain on the reinforcement bars. Typical surface-mount and spot weldable strain meters are presented in Figure 3.4 and Figure 3.5, respectively.

Figure 3.4 Weldable surface-mount strain meter (Slope Indicator, 2013)

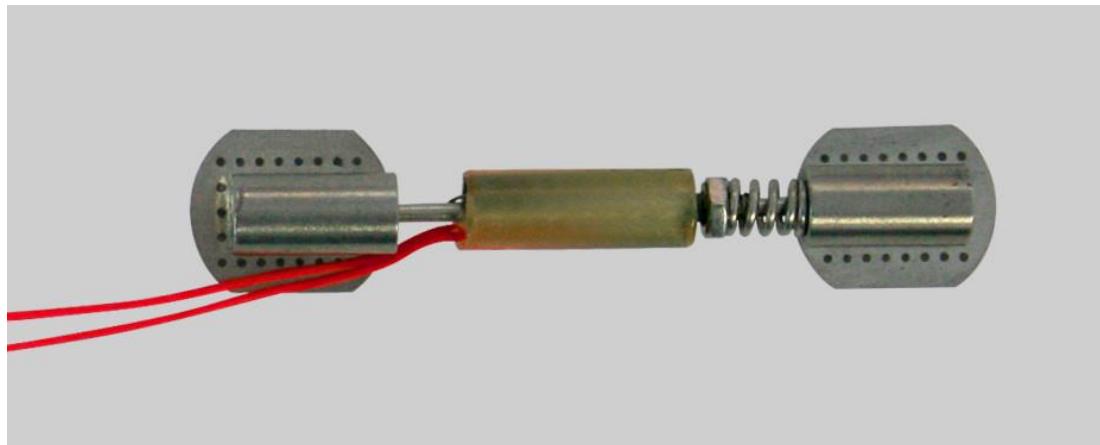

Figure 3.5 Spot weldable strain meter (RST Instruments, 2015)

### 3.2.3 Settlement Cells

Settlement cells are very useful during the construction phase of the dam. They also play an important role during initial filling of the reservoir, since most of settlements are observed at the initial filling of the dams. Settlement cells are also used for

monitoring the vertical movements of the dam body and foundations throughout the lifetime of the structure. During the design of all dams, some settlement is anticipated by the designer by means of either computer-assisted analyses or empirical formulation. Settlement cells are very helpful for verification of the design methods and parameters just after the completion of the dam. A typical vibrating wire settlement cell is presented in Figure 3.6.

Figure 3.6 Vibrating wire settlement cell (Soil instruments, 2014)

Settlement cells can either be hydraulic or electronic (vibrating-wire). The vertical movement within the dam body changes the location of the settlement cell. This

change is then measured by the settlement cell by measurement of the hydrostatic pressure in the chamber of the instrument.

### 3.2.4 Joint Meters

As mentioned before, face slab of a CFRD consists of many individual panels. All panels are mounted to each other; however, these mountings should allow relative movements to some extent. In order to monitor the opening or closing movement of the joints, joint meters are used. A typical one-dimensional joint meter is presented in Figure 3.7.

Figure 3.7 Joint meter (Sisgeo, 2016)

Joint meters can be one, two, or three dimensional. Generally, one or two dimensional joint meters are used to monitor the relative displacement of the individual panels, whereas three dimensional joint meters are preferred to monitor the perimeter joints.

### 3.2.5 Inclinometer

Inclinometers are employed in CFRDs in order to measure the deformation of the face slab. Inclinometers are basically composed of rugged steel or PVC pipes firmly mounted onto the face slab. The pipes have special grooves for driving the measuring probe inside it (Figure 3.8).

Figure 3.8 Inclinometer casing (Roctest, 2016-a)

Just after construction of the face slab and before initial filling, it can be said that the face slab is perfectly flat and there is no deviation on the inclinometer casing. After loading of the face slab, inclinometer casing also deforms with face slab, hence it is firmly mounted. The measuring probes are very sensitive and can record the slightest irregularity while moving inside the inclinometer tubing (see Figure 3.9).

Figure 3.9 Inclinometer probe (Roctest, 2016-b)

### 3.2.6 Piezometers and Weirs

Piezometers are mainly employed to measure the pore water pressure. There are several different types of piezometers from early standpipes to vibrating-wire piezometers which are as small as a fountain pen. They are accurate and simple way to measure the pore water pressure if the correct filter tips are used and installed properly.

In CFRDs, piezometers are mainly placed at foundation level but can also be installed within the dam body. ICOLD (2005) states that the use of piezometers is optional

unless the embankment fill comprises a non-drained material. A number of piezometers for different applications are presented in Figure 3.10.

Figure 3.10 Vibrating wire piezometers (Telemac, 2016)

Weirs are used to measure the rate of the seepage from the face slab and perimeter joint through the dam body. They can be placed where the seepage measurement requires a critical importance. Turbidity measuring sensors are also very beneficial for determining the exact location of the initiation of the leakage. A v-notch weir with its sensor is presented in Figure 3.11.

Figure 3.11 V-Notch weir and vibrating wire sensor (itmsoil, 2013)

### 3.3 Monitoring System Layouts of Existing Dams

Current practices formed by expert judgements have been studied in order to form a basis for the algorithm to be generated as a result of this study. That is why the evaluation of the instrumentation configuration of some existing dams may provide useful information. The instrumentation layout of maximum cross-sections of various CFRDs throughout the world are presented in the following figures.

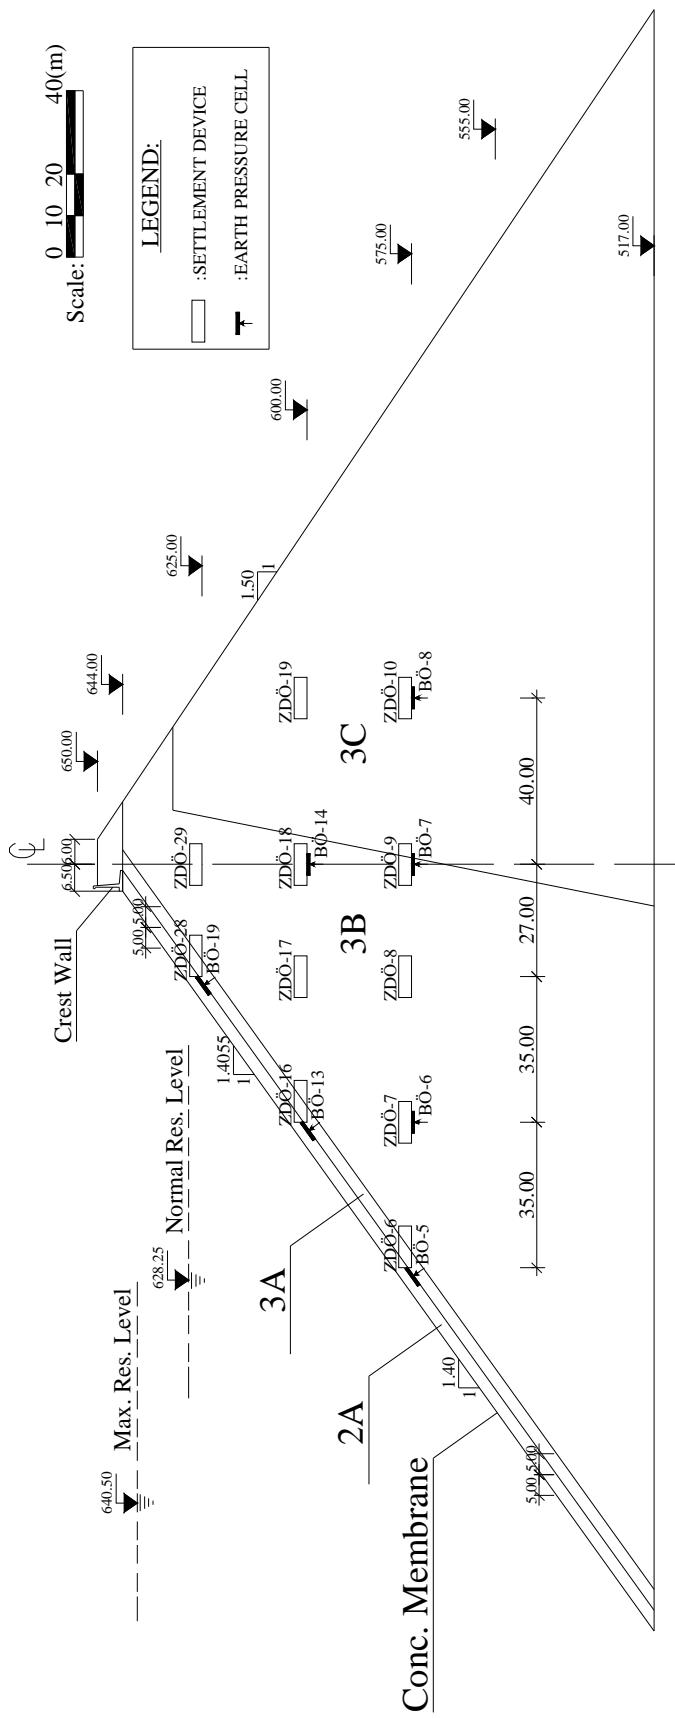

Figure 3.12 Settlement measuring devices and pressure cells in cross-section KM: 0+120.00 of Kürtün Dam (Özkuzukiran, 2005)

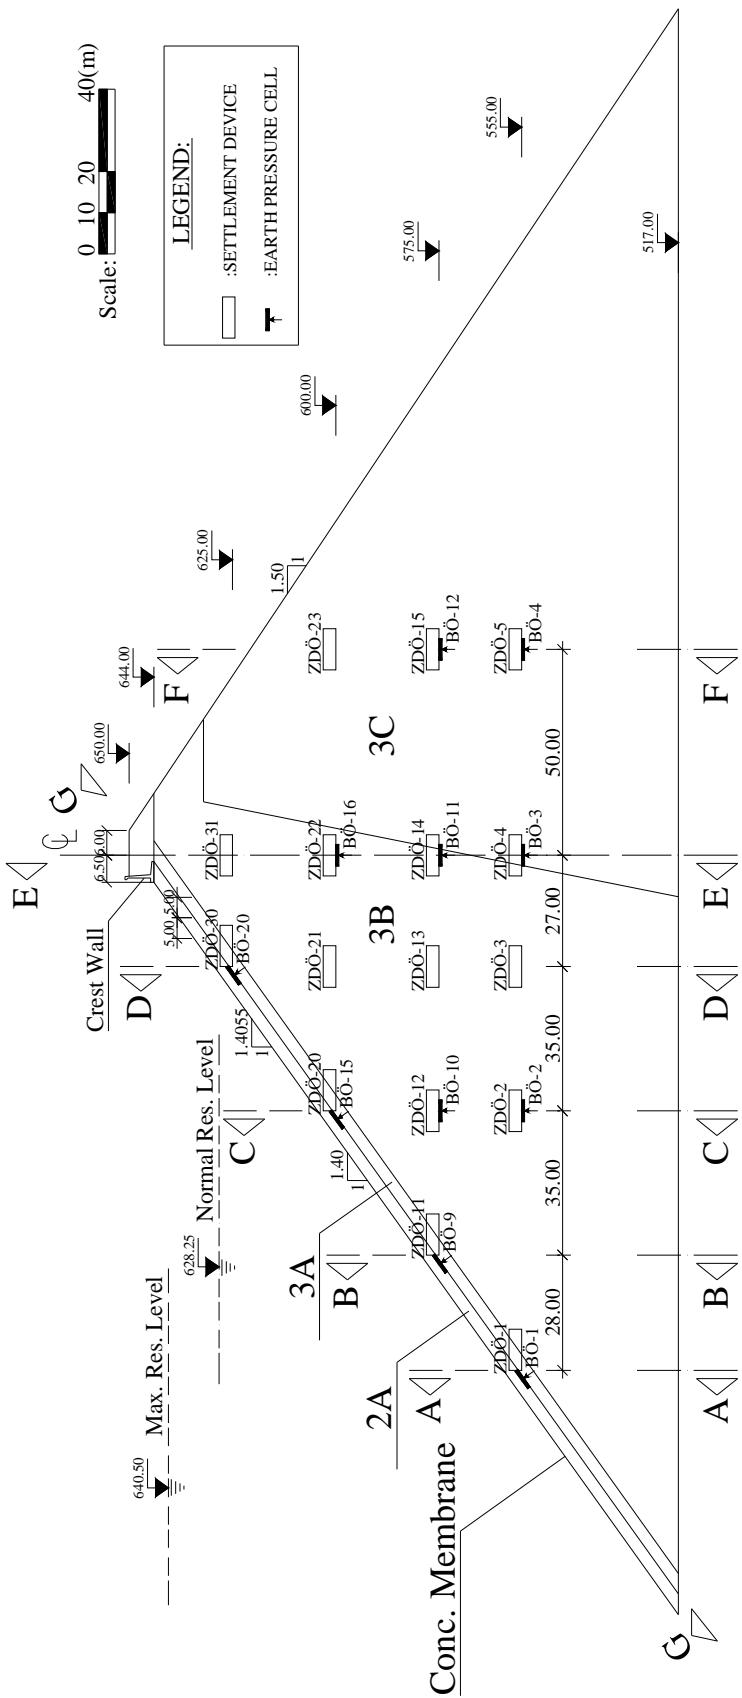

Figure 3.13 Settlement measuring devices and pressure cells in cross-section KM: 0+180.00 of Kürtün Dam (Özkuzukiran, 2005)

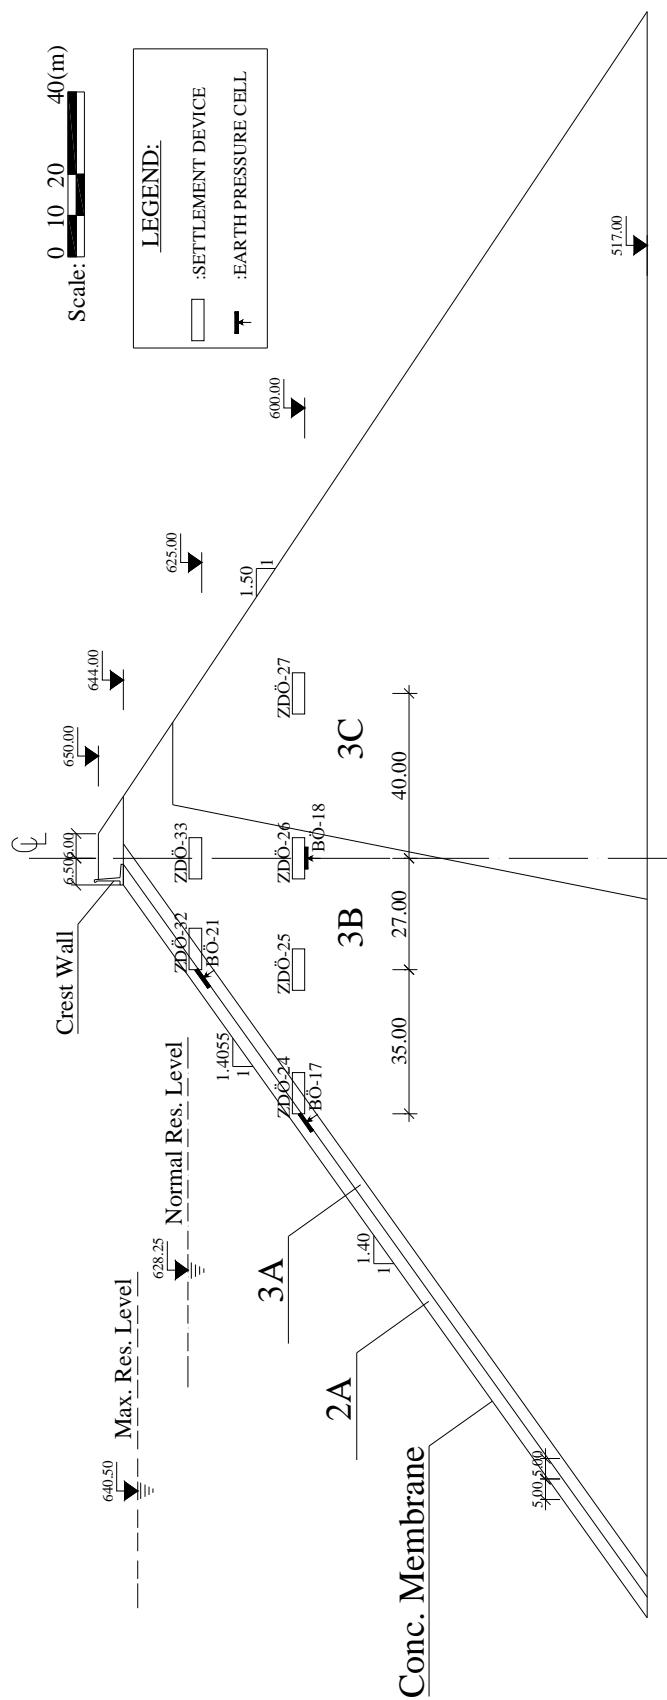

Figure 3.14 Settlement measuring devices and pressure cells in cross-section KM: 0+240.00 of Kürtün Dam (Özkuzukiran, 2005)

### 3.4 Analysis of the Trends of Existing Configurations

A number of existing CFRDs were analysed according to their number of horizontal layers where sensors are placed,  $M$ , and total number of sensors,  $N_T$ , to search a possible relationship between the dam height,  $H_f$ , and  $M$  and  $N_T$ . The analysed data are presented in Table 3.2.

Table 3.2 Instrumentation configurations of some CFRDs

Dam	$H_f$ (m)	M	$N_T$
Bastyan	75	3	4
Berg River	67	3	12
Kürtün	133	4	21
La Yesca	220	4	45
Lower Pieman	122	4	5
Mackintosh	75	3	6
Murchison	94	3	4
Shuibuya	233	5	38
Tanyeri	103.5	3	22
Tianshengqiau-I	176	4	16
Tullabardine	26	3	4
Xingo	140	3	12
Zipingpu	156	4	30

Linear regression analyses were conducted for the aforementioned relationship with  $R^2$  values of 0.70 for the following equations:

$$M = 0.009H_f + 2.408 \quad (3.1)$$

$$N_T = 0.189H_f - 6.722 \quad (3.2)$$

where  $H_f$  is in meters.

It should be noted that the above relationships give only a preliminary information and lack to provide information about the number of sensors on each layer and the locations of sensors within the dam cross-section.

### **3.5 Concluding Remarks**

Lifetime monitoring of a CFRD will provide essential data for assessing the dam behaviour and allow sufficient time for remedial actions to be taken before the occurrence of any unwanted incident. Monitoring is also vital for the verification of the design and development of the future designs as the current practices mainly depend on the empirical approaches and expert judgements (Yanmaz and Ari, 2011).

As explained before in detail, CFRDs are prone to overtopping and seepage induced failures. These failure modes in fact are related with the unexpected movement and excessive settlement of the dam body. Settlement may lead to the decrease of freeboard which increases the risk of overtopping and cracking of the face slab causing leakage problems. That is why the scope of this study is to develop a decision support system for optimal design of stress monitoring system.

In the following section, the developmental stages of an algorithm for positioning the total pressure cells is considered. Pore water pressure and uplift measuring sensors are omitted from the decision support system because in most of the designs, face slabs are considered as completely impermeable. Because of the zero uplift forces within the completely dry fill material, effective stresses are equal to the total stresses. From this fact, it is believed that an abrupt change in the effective stress readings from more than one sensor could provide information about a possible leakage problem from the impervious upstream face slab. Therefore, giving priority to the use of total pressure cells is reasonable.

The deformations and the movement of the face slab and individual panels can be monitored with inclinometers, tiltmeters and crack meters. However, the detailed analyses and the possible optimal instrumentation scheme of the face slab is out of scope of this study. In the light of the facts stated above, an algorithm is proposed for optimal layout of stress measuring sensors in the Chapter 4.

## **CHAPTER 4**

### **DEVELOPMENT OF OPTIMIZATION ALGORITHM**

#### **4.1 Scope and Expected Benefits of the Study**

The scope of this study is to find the optimal configuration of the internal stress monitoring system of a CFRD. The algorithm will provide the required number of sensors and the location of the layers to be equipped with these sensors within a CFRD cross-section. It will also give information about the number and the location of the stress measuring sensors.

In order to achieve the desired scope of the study, the proposed algorithm uses the quality of the information by measuring the difference between the true stress distribution obtained via software used and the measured stress distribution. It also takes into account the cost of the proposed monitoring system configuration by considering both the cost of the sensor and the cost of the sensor cable.

The expected benefit of this algorithm is to provide the designers a tool which can be used fast and effortlessly to obtain a configuration for the stress monitoring system of a CFRD. It is believed that this configuration would provide adequate long-time information for both realistic assessment of dam behaviour and verification of structural models. It is obvious that every project in water resources engineering is unique; thus the monitoring requirement may vary from case to case. However, the user would get an initial idea about the instrumentation configuration and then modify it according to the local characteristics and requirements of the project.

## **4.2 PLAXIS**

Effective stress distribution throughout the dam body under a particular loading condition can be determined from a software. To this end, PLAXIS (Brinkgreve and Broere, 2008) was used.

### **4.2.1 Brief History of PLAXIS**

PLAXIS development was started in 1987 by the Technical University of Delft with the help of the Dutch Department of Public Works and Water Management (Brinkgreve and Broere, 2008). The main objective was to form a user-friendly code to solve 2D finite element problems. In 1993, PLAXIS b.v was founded in order to satisfy the growing requirements of business (Brinkgreve and Broere, 2008). The development of PLAXIS continued steadily by covering most of the areas of geotechnical engineering and even 3D finite element codes are released.

### **4.2.2 Basics of PLAXIS**

PLAXIS 2D is a widely used geotechnical engineering tool, which includes PLAXIS Dynamics and PLAXIS PlaxFlow. PLAXIS 2D is a finite element analysis package aimed to analyse various geotechnical applications. With the help of the advanced models, PLAXIS 2D package can solve the non-linear, anisotropic, and time-dependent behaviour of soil (Brinkgreve et.al, 2010).

The main features of PLAXIS are as follows (Brinkgreve et.al, 2010):

- Different structural elements (anchors, plates, and geogrids)
- Elasto-plastic behaviour for structural elements
- Unlimited combination of forces (point loads and distributed loads)

- Automatic identification of soil layers
- Automatic finite element mesh generation with updated mesh (Lagrange) analyses
- Consolidation and groundwater analyses
- Safety factor analysis

The Basic soil models used in PLAXIS are as follows:

- Linear Elastic
- Mohr-Coulomb

More realistic and advanced soil models are also employed in PLAXIS:

- Compression and shear hardening (Hardening soil model)
- Creep behaviour
- Cam-Clay Model
- User-defined models

In early times, rockfill is simply modelled as a linear elastic material. However, this is not a realistic approach because rockfill behaviour is highly non-linear. Duncan and Chang (1970) developed a hyperbolic model for rockfill and is updated by Kulhawy and Duncan (1972). This model, however, does not include plastic behaviour of rockfill. In order to take the plastic behaviour of rockfill into account, hardening soil model (compression and shear hardening) was developed on the basis of hyperbolic approach of Duncan and Chang (1970). The most important difference is that this model uses theory of plasticity rather than theory of elasticity. That is why PLAXIS is generally used for modelling of CFRDs (Özkuzukiran, 2005).

PLAXIS Dynamics module is used to analyse the effects of seismic loading and the vibrations of the nearby construction activities. With the help of dynamic simulations, the effects of wave propagation in soil media can be estimated (Brinkgreve et.al, 2010).

The features of PLAXIS Dynamics module are as follows (Brinkgreve et.al, 2010):

- Absorbent boundaries
- Wave velocities
- Dynamic loading inputs from
- Harmonic loads
- Real earthquake data
- User-defined loading
- Solution in a predefined time domain
- Automatic time stepping
- Displacements
- Velocities
- Time curves
- Spectra

PLAXIS PlaxFlow module is specifically designed to analyse the time-dependent groundwater flow. It is obvious that groundwater flow also has an indispensable effect on the possible deformations of the saturated and partially saturated soils. With the help of this module, time-dependent effects of flow and pore water pressures are also taken into account during simulations of deformations. These time-dependent analyses are based on Biot's theory of consolidation (Brinkgreve et.al, 2010).

The main features of PLAXIS PlaxFlow module are as follows (Brinkgreve et.al, 2010):

- Modelling with screens, wells and drains
- Different boundary conditions (time-dependent, linear, harmonic, and user-defined)
- Prescribed heads
- Inclusion of inflow and outflow
- Inclusion of precipitation and evaporation
- Different models for soil (linear and Van Genuchten)
- Anisotropic flow conditions
- Automatic time stepping
- Combining results with deformation analyses.

### **4.2.3 Modelling with PLAXIS**

#### ***4.2.3.1 General Modelling Features***

Points: They are the beginnings and ends of the lines and also used for locating structural elements and forces (Brinkgreve and Broere, 2008).

Lines: They are used to define the geometry, boundaries, soil discontinuities, structures, and constructional stages (Brinkgreve and Broere, 2008).

Clusters: They are the areas formed by closed set of lines. The code forms it automatically and assumes the soil properties in a cluster to be uniform (Brinkgreve and Broere, 2008).

Elements: Before calculations, PLAXIS should form the finite element mesh and form triangular elements. These triangles can be divided into 15-node elements or 6-node

elements. The former provides accuracy in calculations, whereas the latter is useful for quick computing (Brinkgreve and Broere, 2008).

Nodes: In finite element analysis, displacements in 2D are calculated for all nodes (Brinkgreve and Broere, 2008).

Stress Points: 15-node triangular elements consist of 12 stress points and 6-node triangular elements consist of 3 stress points (Brinkgreve and Broere, 2008). The nodes and stress points are shown in Figure 4.1.

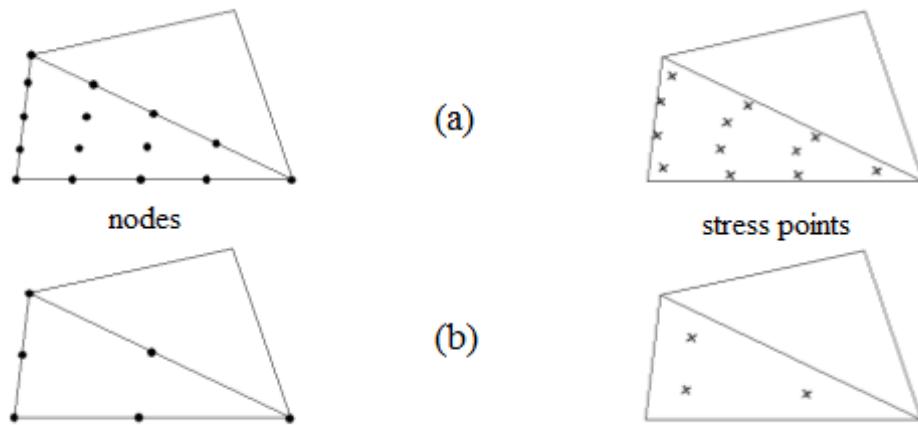

Figure 4.1 Nodes and stress points for (a) 15-node (b) 6-node triangular elements  
(Brinkgreve and Broere, 2008)

#### 4.2.3.2 Input Procedure

In PLAXIS four types of inputs are available to user (Brinkgreve and Broere, 2008):

- Geometry objects
- Text
- Values
- Selections

In Figure 4.2 and Figure 4.3, the main input window and toolbars of PLAXIS are shown, respectively.

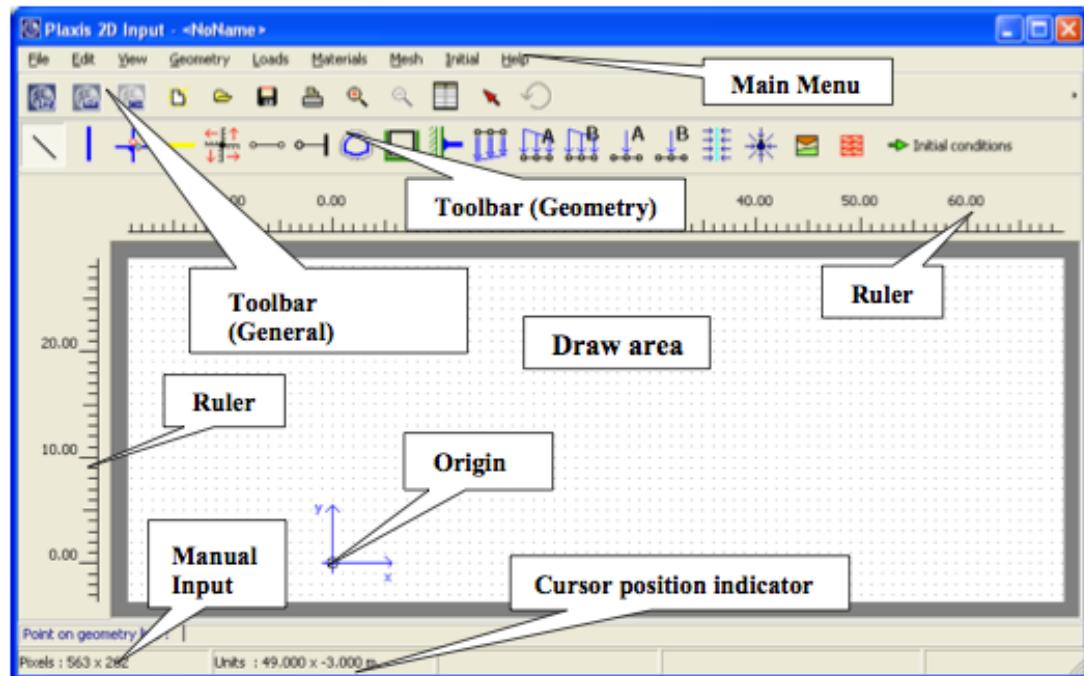

Figure 4.2 Main input window (Brinkgreve and Broere, 2008)

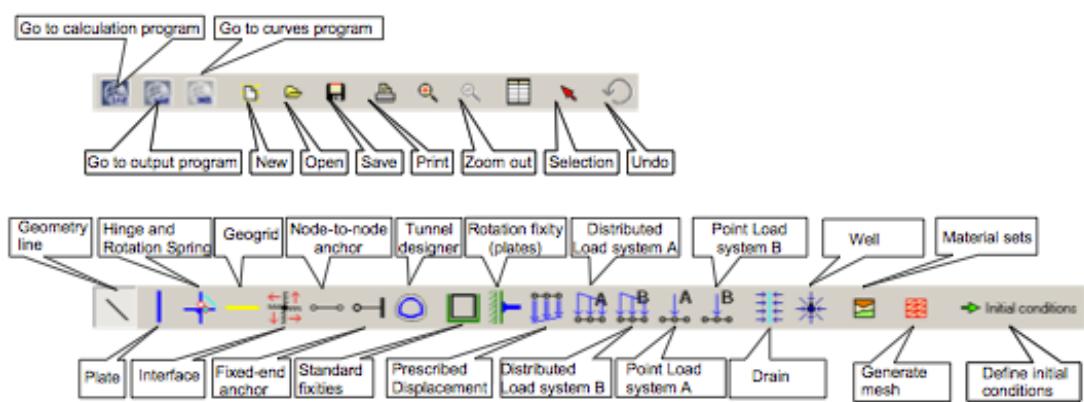

Figure 4.3 Input window toolbar (Brinkgreve and Broere, 2008)

#### 4.2.3.3 Calculations Module

After entering the input data (geometry, loads, etc.), the user forms the mesh and saves the input file. The calculate button in toolbar closes the input window and opens the calculations window of PLAXIS. It is used to define and execute the calculation phases (Brinkgreve and Broere, 2008). Typical view of calculations window is shown in Figure 4.4.

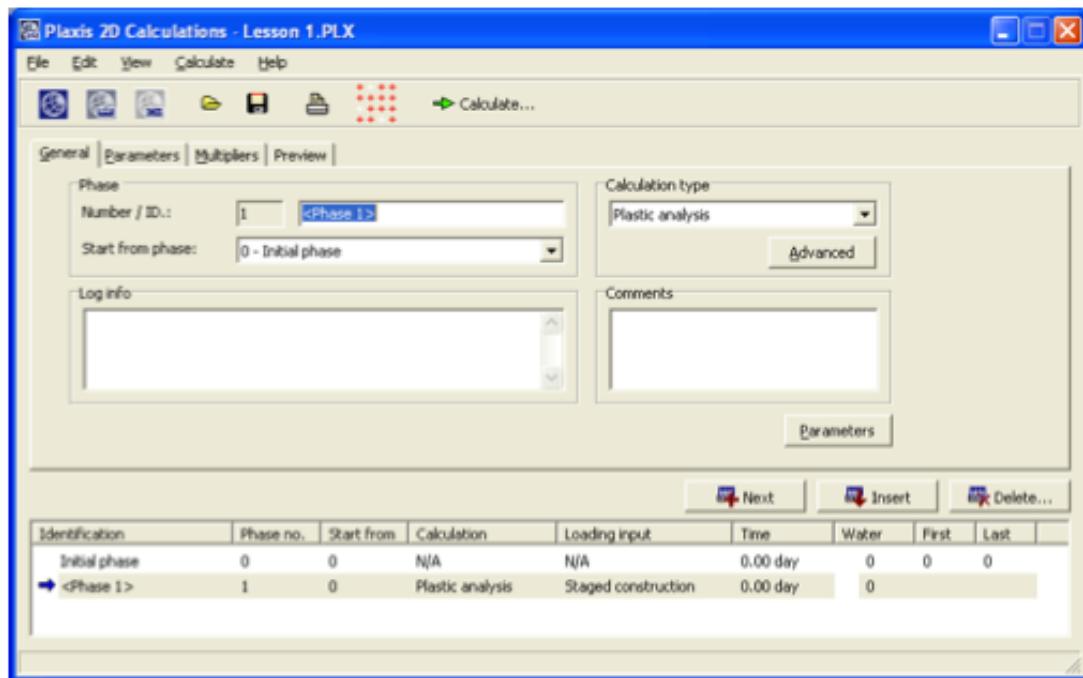

Figure 4.4 Calculations window (Brinkgreve and Broere, 2008)

There are several tabs provided for defining the calculation phase. These can be loading, construction, excavation, or consolidation phases (Brinkgreve and Broere, 2008).

#### 4.2.3.4 Viewing Results

Upon completion of the calculations, one can get the results of the analyses in the output window. In the output window, the user can get the resultant displacements and stresses in the full geometry or in a desired cross-section and in structural elements (Brinkgreve and Broere, 2008).

A view of a deformed mesh in output windows is presented in Figure 4.5.

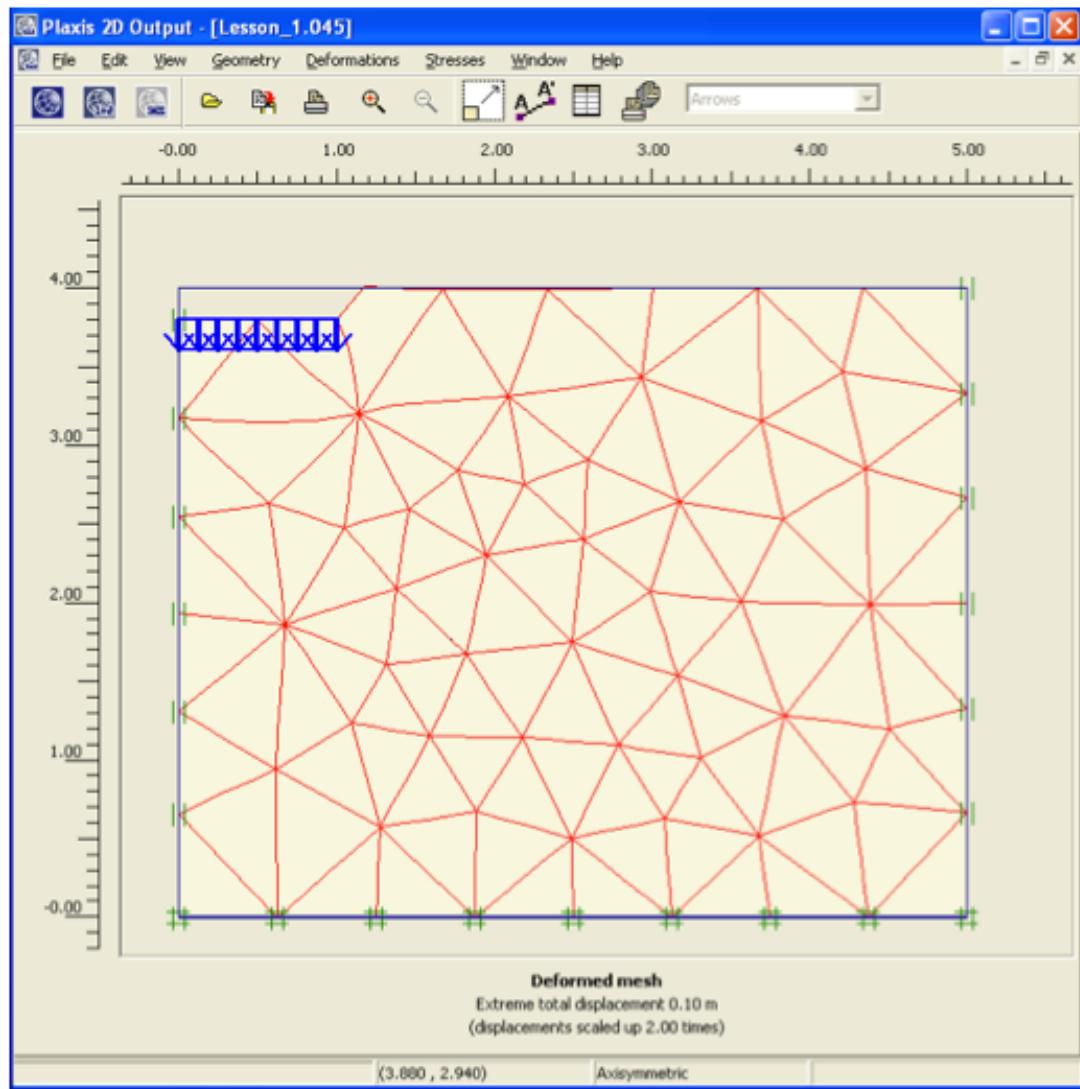

Figure 4.5 Deformed mesh (Brinkgreve and Broere, 2008)

### 4.3 Assumptions of the Study

The following assumptions are accepted throughout this study unless otherwise stated:

- i. Dam body is assumed as homogeneous fill, which is characteristic composition of such dams.
- ii. Reservoir level is full, upstream slab is intact and impervious (no cracks initially)
- iii. The CFRD cross-sections are symmetrical having side slopes of 1V:1.5H on upstream and downstream faces.
- iv. 9 cross-sections were analysed, starting from 40 m up to 200 m-high from thalweg and increasing with 20 m increments.
- v. The width of the crest of the CFRD cross-sections are constant and 15 m for all heights.
- vi. The relation between the dam height measured from thalweg ( $H_t$ ) versus the height from foundation ( $H_f$ ) was obtained with reference to the geometric characteristics of various existing rockfill dams in Turkey (provided in Appendix B) and formulated as ( $R^2=0.9484$ ):

$$H_f = 1.16H_t \quad (4.1)$$

where  $H_f$  and  $H_t$  are in meters.

- vii. The rockfill was modelled with hardening soil model in PLAXIS. The material type was defined as “drained” with an equal unsaturated and saturated specific weight of 27.79 kN/m<sup>3</sup> and with a reference cohesion value of 1.00 KN/m<sup>2</sup>.
- viii. Stiffness parameters of PLAXIS hardening soil model are provided in Figure 4.6.
- ix. The impervious upstream slab was modelled as “elastic plate” with the properties presented in Figure 4.7.

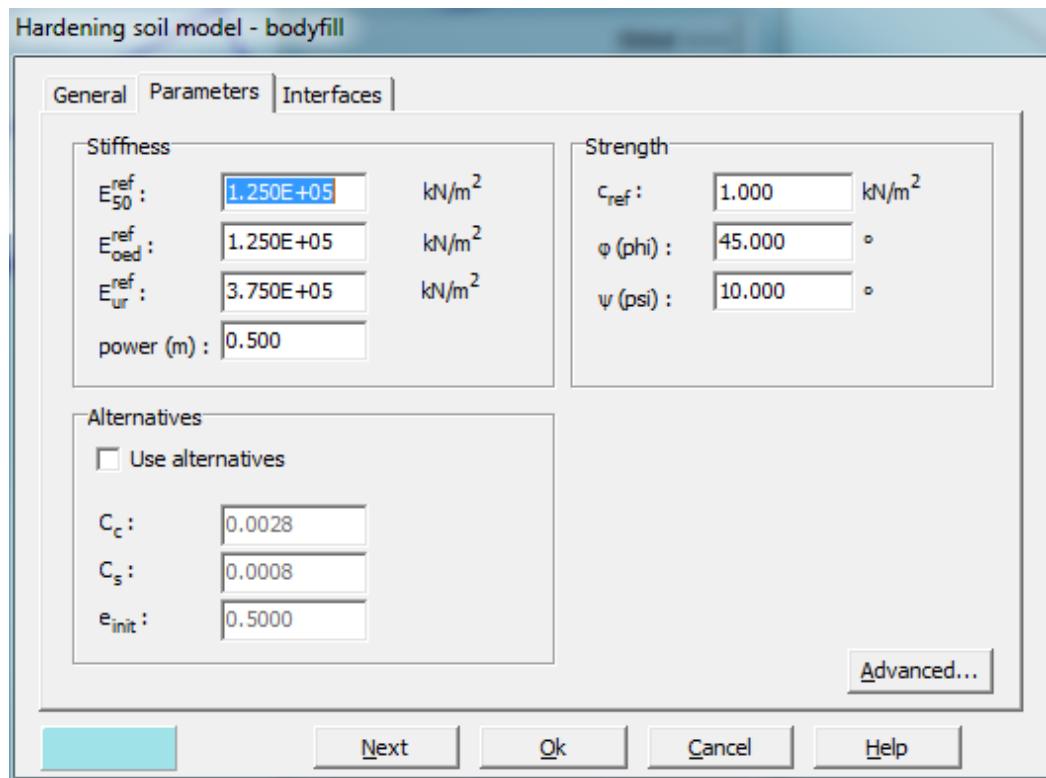

Figure 4.6 Hardening soil model parameters

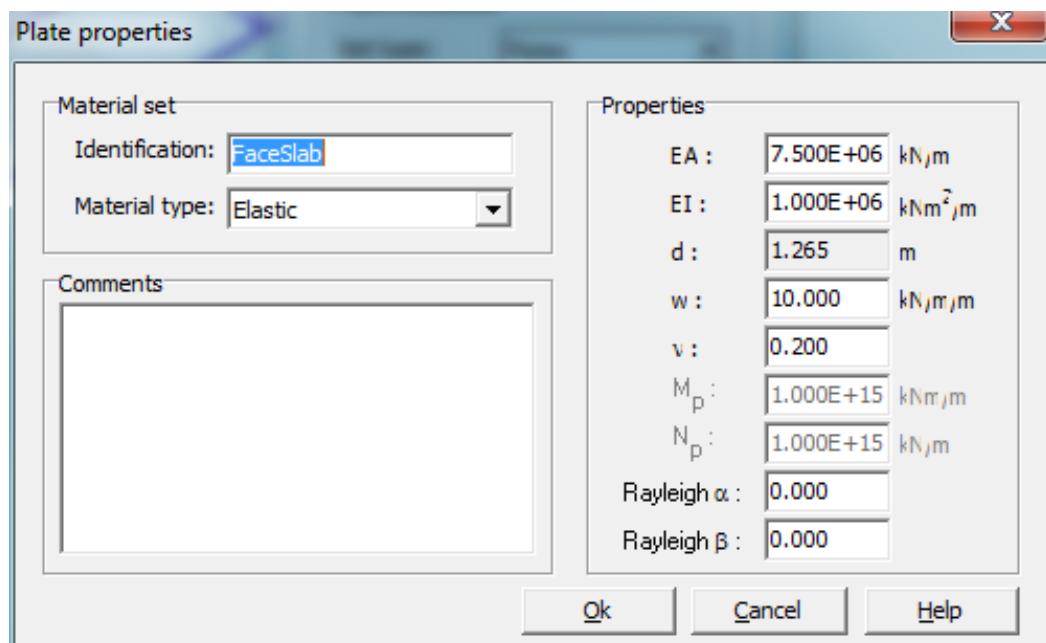

Figure 4.7 Parameters for impervious upstream slab

- x. The loading case includes self-weight of the dam and the hydrostatic forces resulted from a reservoir at maximum operating level. The maximum water level is assumed to be 5 m below the dam crest elevation. The loads not considered herein were discussed in sensitivity analysis section (Section 4.7).
- xi. Sensors are placed on a layer symmetrically with equal distances between them.

## 4.4 Vertical Projection of Sensors

### 4.4.1 Introductory Remarks

Study of vertical projection of the effective stress distribution at the mid-axis of the dam body provides a mean for determining the number of horizontal layers to be equipped with sensors within the dam body. The readings obtained from the sensors will be useful for determining the horizontal pressure and deformation on a vertical projection.

Three different approaches were considered in the developmental stage of the algorithm. Figure 4.8 represents the sectional details of the effective stress distributions. The cross-section “a-a” is used for determining the number of layers for instrumentation, whereas the cross-section “b-b” is utilized for obtaining the number of sensors at a particular layer. In this figure,  $P'_h$  and  $P'_v$  stand for effective horizontal and vertical force, respectively.

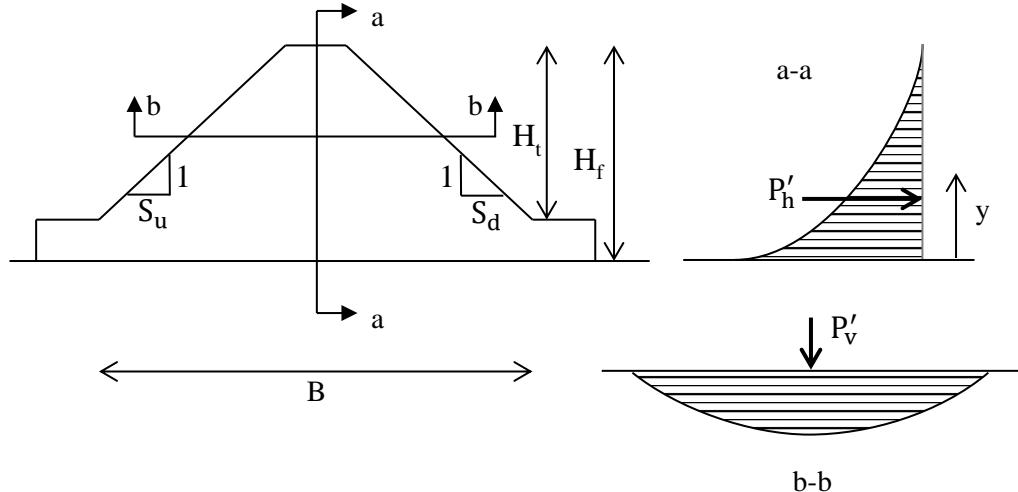

Figure 4.8 Sectional details of the effective stress distributions

#### 4.4.2 Effective Stress Variation on a Vertical Plane

Variation of the effective stress acting on section a-a (Figure 4.8) with respect to varying dam height was modelled and generalized by the regression analysis. Effective stress values were obtained from PLAXIS and provided in Appendix C. Dimensionless parameters are formed and the relation between the effective pressure variations for different dam heights were defined as following:

$$f\left(\frac{y}{H_f}\right) = \frac{\sigma'_h}{\gamma B} \quad (4.2)$$

where;

$y$  : height from the foundation level of the dam (Figure 4.8),

$H_f$  : height of the dam from foundation (Figure 4.8),

$\gamma$  : specific weight of water,

$B$  : base width of the dam (Figure 4.8), and

$\sigma'_h$  : horizontal effective stress obtained from PLAXIS.

Base width of the dam is computed by considering the 1V:1.5H symmetric side slopes and 15 m width of dam crest:

$$B = 3H_t + 15 \quad (4.3)$$

where  $H_t$  and  $B$  are in meters.

The results of the effective stress distributions on section a-a gathered from PLAXIS were analysed for obtaining a dimensionless relationship (Figure 4.9 and Table 4.1).

Dimensionless representation of the effective stress distribution of the dam along section (a-a) having  $H_t$  ranging from 40 m to 200 m can be expressed by ( $R^2=0.9996$ ):

$$\frac{\sigma'_h}{\gamma B} = 0.13 \left( \frac{y}{H_t} \right)^3 - 0.34 \left( \frac{y}{H_t} \right)^2 + 0.65 \left( \frac{y}{H_t} \right) - 0.52 \quad (4.4)$$

where;

$H_t$  : height of dam from thalweg.

The horizontal projected force,  $P'_h$ , were computed analytically from distribution of the horizontal effective stresses,  $\sigma'_h$ . The results are presented in Table 4.2, and in Figure 4.10 for the aforementioned dam heights.

Table 4.2 Projected horizontal effective forces versus  $H_t$

$H_t$ (m)	$P'_h$ (kN/m)
40	14688.28
60	31717.55
80	55307.06
100	84999.08
120	120132.75
140	162415.60
160	211269.55
180	266184.17
200	326790.43

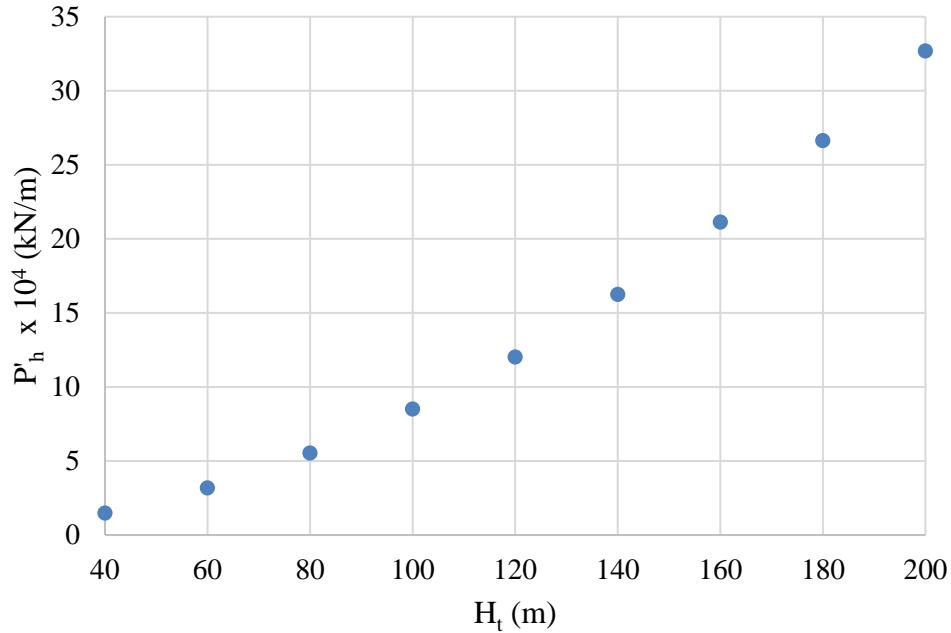

Figure 4.10 Projected horizontal effective forces versus  $H_t$

The areas under the pressure distribution curves were computed for the aforementioned dam heights to obtain the projected force,  $P'_h$ , with  $R^2=0.9999$ :

$$P'_h = 7.86H_t^2 + 64.34H_t - 379.63 \quad (4.5)$$

where  $H_t$  is in meters and  $P'_h$  is in kN/m

#### 4.4.3 The First Approach

Sensor outputs are used to estimate the true horizontal effective stress distribution as accurate as possible. The sensors are located symmetrically inside the dam body and provide information about the point loads at various points on the cross-section. However, no sensors would provide data about the end points (top and bottom points) of the cross-section. Horizontal pressure on the crest of the dam can be taken as zero. The stress distribution curves between sensors are assumed to be linear. In this approach, the stress distribution below the lowest sensor is assumed as continuous with

the same slope before the lowest sensor till the base of the dam cross-section (See Figure 4.11 and Figure 4.12).

### **1-Layer Formulation**

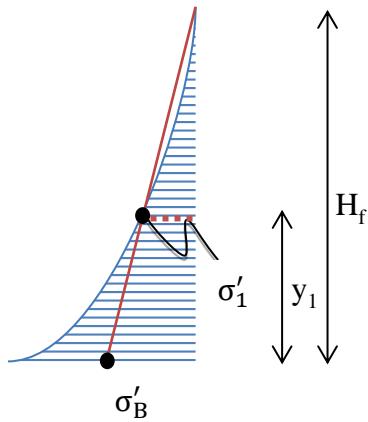

Figure 4.11 Stress distribution modelling with 1 layer

The areas under the effective stress distribution are obtained using the following formulation:

$$\frac{\sigma'_1}{(H_f - y_1)} = \frac{\sigma'_B}{H_f} \quad \sigma'_B = \frac{\sigma'_1 H_f}{(H_f - y_1)} \quad (4.6)$$

$$P'_1 = \frac{\sigma'_B H_f}{2} \quad (4.7)$$

$$P'_1 = \frac{\sigma'_1 H_f^2}{2(H_f - y_1)} \quad (4.8)$$

### 2-Layer Formulation

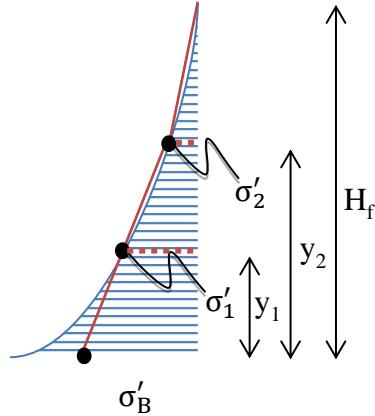

Figure 4.12 Stress distribution modelling with 2 layers

$$P'_2 = \frac{\sigma'_2(H_f - y_2)}{2} + \sigma'_2 y_2 + \frac{y_2^2(\sigma'_1 - \sigma'_2)}{2(y_2 - y_1)} \quad (4.9)$$

### 3-Layer Formulation

$$P'_3 = \frac{\sigma'_3(H_f - y_3)}{2} + \frac{(\sigma'_3 + \sigma'_2)(y_3 - y_2)}{2} + \sigma'_2 y_2 + \frac{y_2^2(\sigma'_1 - \sigma'_2)}{2(y_2 - y_1)} \quad (4.10)$$

### 4-Layer Formulation

$$\begin{aligned} P'_4 = & \frac{\sigma'_4(H_f - y_4)}{2} + \frac{(\sigma'_4 + \sigma'_3)(y_4 - y_3)}{2} + \frac{(\sigma'_3 + \sigma'_2)(y_3 - y_2)}{2} \\ & + \sigma'_2 y_2 + \frac{y_2^2(\sigma'_1 - \sigma'_2)}{2(y_2 - y_1)} \end{aligned} \quad (4.11)$$

### 5-Layer Formulation

$$P_5' = \frac{\sigma'_5(H_f - y_5)}{2} + \frac{(\sigma'_5 + \sigma'_4)(y_5 - y_4)}{2} + \frac{(\sigma'_4 + \sigma'_3)(y_4 - y_3)}{2} \\ + \frac{(\sigma'_3 + \sigma'_2)(y_3 - y_2)}{2} + \sigma'_2 y_2 + \frac{y_2^2(\sigma'_1 - \sigma'_2)}{2(y_2 - y_1)} \quad (4.12)$$

### 6-Layer Formulation

$$P_6' = \frac{\sigma'_6(H_f - y_6)}{2} + \frac{(\sigma'_6 + \sigma'_5)(y_6 - y_5)}{2} + \frac{(\sigma'_5 + \sigma'_4)(y_5 - y_4)}{2} \\ + \frac{(\sigma'_4 + \sigma'_3)(y_4 - y_3)}{2} + \frac{(\sigma'_3 + \sigma'_2)(y_3 - y_2)}{2} + \sigma'_2 y_2 + \frac{y_2^2(\sigma'_1 - \sigma'_2)}{2(y_2 - y_1)} \quad (4.13)$$

#### 4.4.4 The Second Approach

The only difference of the second approach from the first one is that the effective stress distribution at the last segment is assumed to be constant and the same as the lowest sensor readout (See Figure 4.13, Figure 4.14, and Figure 4.15).

### 1-Layer Formulation

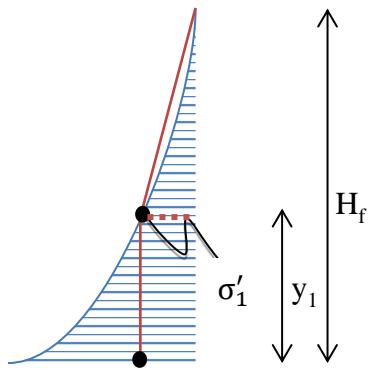

Figure 4.13 Stress distribution modelling with 1 layer

$$P'_1 = \frac{\sigma'_1(H_f - y_1)}{2} + \sigma'_1 y_1$$

$$P'_1 = \frac{\sigma'_1(H_f + y_1)}{2} \quad (4.14)$$

### 2-Layer Formulation

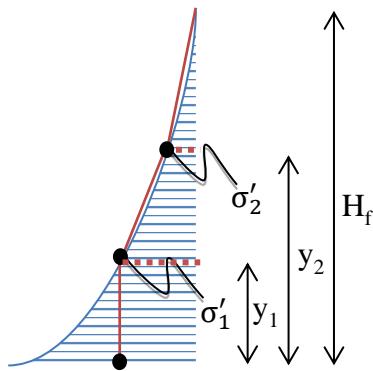

Figure 4.14 Stress distribution modelling with 2 layers

$$P'_2 = \frac{\sigma'_2(H_f - y_2)}{2} + \frac{(\sigma'_2 + \sigma'_1)(y_2 - y_1)}{2} + \sigma'_1 y_1$$

$$P'_2 = \frac{\sigma'_2 H_f - \sigma'_2 y_2 + \sigma'_1 y_2 - \sigma'_1 y_1 + \sigma'_2 y_2 - \sigma'_2 y_1}{2} + \sigma'_1 y_1$$

$$P'_2 = \frac{\sigma'_2 H_f + \sigma'_1 y_2 - \sigma'_2 y_1 + \sigma'_1 y_1}{2}$$

$$P'_2 = \frac{\sigma'_2(H_f - y_1) + \sigma'_1(y_2 + y_1)}{2} \quad (4.15)$$

### 3-Layer Formulation

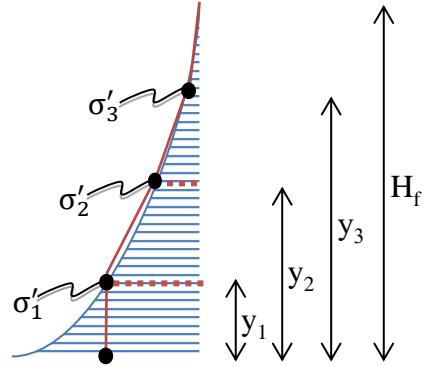

Figure 4.15 Stress distribution modelling with 3 layers

$$P'_3 = \frac{\sigma'_3(H_f - y_3)}{2} + \frac{(\sigma'_3 + \sigma'_2)(y_3 - y_2)}{2} + \frac{(\sigma'_2 + \sigma'_1)(y_2 - y_1)}{2} + \sigma'_1 y_1$$

$$P'_3 = \frac{\sigma'_3(H_f - y_2) + \sigma'_2(y_3 - y_1) + \sigma'_1(y_2 + y_1)}{2} \quad (4.16)$$

### 4-Layer Formulation

$$\begin{aligned} P'_4 &= \frac{\sigma'_4(H_f - y_4)}{2} + \frac{(\sigma'_4 + \sigma'_3)(y_4 - y_3)}{2} + \frac{(\sigma'_3 + \sigma'_2)(y_3 - y_2)}{2} \\ &\quad + \frac{(\sigma'_2 + \sigma'_1)(y_2 - y_1)}{2} + (\sigma'_1 y_1) \end{aligned}$$

$$P'_4 = \frac{\sigma'_4(H_F - y_3) + \sigma'_3(y_4 - y_2) + \sigma'_2(y_3 - y_1) + \sigma'_1(y_2 + y_1)}{2} \quad (4.17)$$

### 5-Layer Formulation

$$P'_5 = \frac{\sigma'_5(H_F - L_4) + \sigma'_4(y_5 - y_3) + \sigma'_3(y_4 - y_2) + \sigma'_2(y_3 - y_1)}{2} + \frac{\sigma'_1(y_2 + y_1)}{2} \quad (4.18)$$

### 4.4.5 The Third Approach

This approach assumes that base and crest level horizontal effective stresses are known and the sensors located between base and crest are used to determine the shape of the stress distribution. More points provide more accurate representation of the shape of the stress distribution (See Figure 4.16, Figure 4.17, and Figure 4.18).

### 1-Layer Formulation

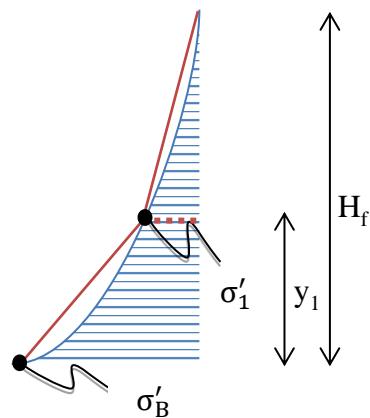

Figure 4.16 Stress distribution modelling with 1 layer

$$P'_1 = \frac{\sigma'_B y_1 + \sigma'_1 H_f}{2} \quad (4.19)$$

### 2-Layer Formulation

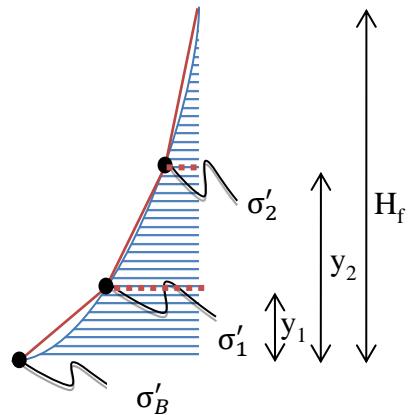

Figure 4.17 Stress distribution modelling with 2 layers

$$P'_2 = \frac{y_1(\sigma'_B + \sigma'_1)}{2} + \frac{(\sigma'_1 + \sigma'_2)(y_2 - y_1)}{2} + \frac{\sigma'_2(H_f - y_2)}{2}$$

$$P'_2 = \frac{\sigma'_B y_1 + \sigma'_1 y_2 - \sigma'_2 y_1 + \sigma'_2 H_f}{2} \quad (4.20)$$

### 3-Layer Formulation

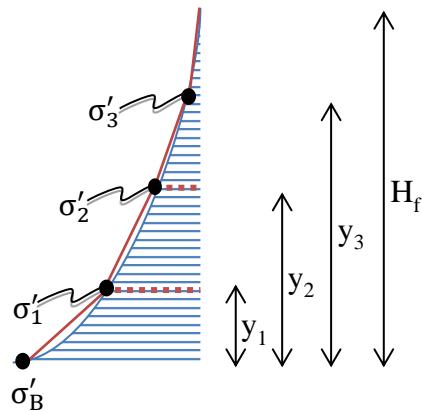

Figure 4.18 Stress distribution modelling with 3 layers

$$P'_3 = \frac{y_1(\sigma'_B + \sigma'_1)}{2} + \frac{(\sigma'_1 + \sigma'_2)(y_2 - y_1)}{2} + \frac{(\sigma'_2 + \sigma'_3)(y_3 - y_2)}{2} + \frac{\sigma'_3(H_f - y_3)}{2}$$

$$P'_3 = \frac{\sigma'_B y_1 + \sigma'_1 y_2 - \sigma'_2 y_1 + \sigma'_2 y_3 - \sigma'_3 y_2 + \sigma'_3 H_f}{2} \quad (4.21)$$

#### 4.4.6 Evaluation of the Error of Approaches

Errors of the approaches were evaluated by comparing the modelled areas with the true areas below the effective stress distributions and presented in Table 4.3, Table 4.4, and Table 4.5.

As it can be observed from these tables, the third approach gives the lowest error. Thus the third approach was chosen to be employed in the following algorithm development process. The next part is devoted to the description of the horizontal projection of the sensors on a layer.

Table 4.3 Percent error of the first approach

## 4.5 Horizontal Projection of Sensors

### 4.5.1 Introductory Remarks

Effective stress distribution of any horizontal layer under the loading case concerned can be obtained from the finite element analysis package, PLAXIS. Shape of the effective stress distribution of a symmetric homogeneous CFRD cross-section tends to be a high-degree polynomial (Figure 4.19).

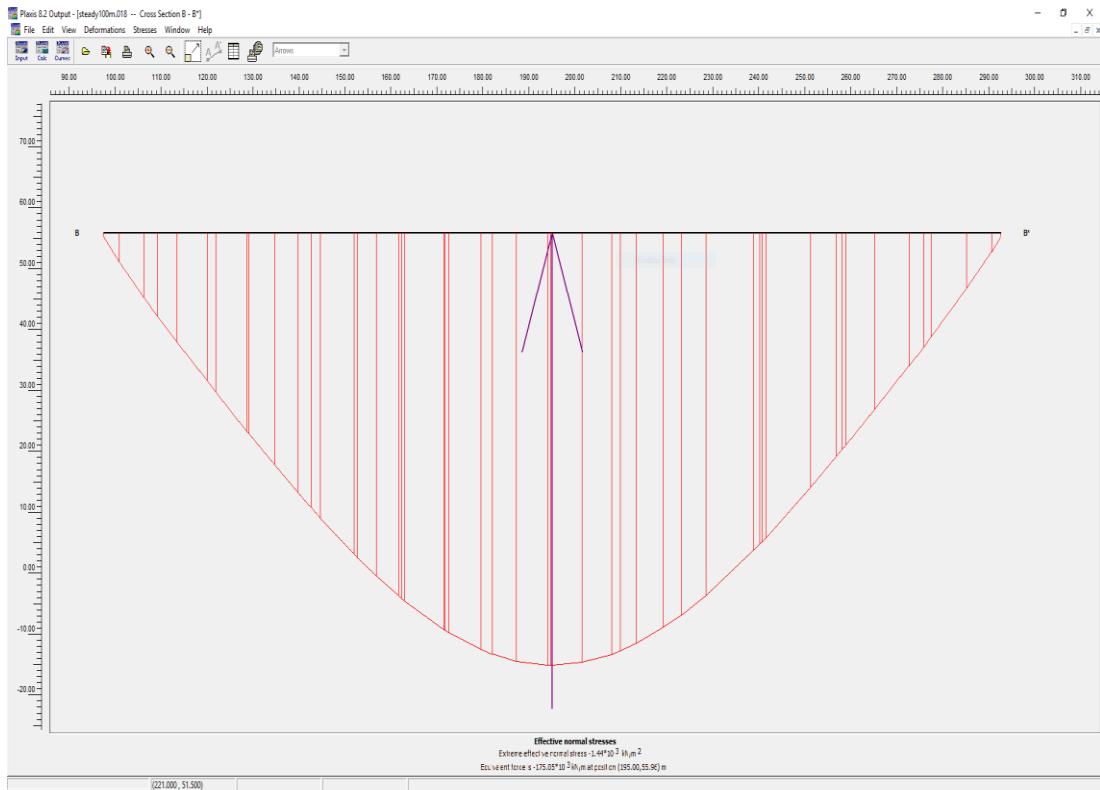

Figure 4.19 PLAXIS output showing the effective stress distribution

#### 4.5.2 Modelling of Effective Stress Distribution

The datasets of the effective stress distribution were obtained from the PLAXIS. The equation of the effective stress distribution at any horizontal layer can be formulated by:

$$\sigma'_v(x) = ax^6 + bx^5 + cx^4 + dx^3 + ex^2 + fx + g \quad (4.22)$$

where  $a, b, c, d, e, f$ , and  $g$  are coefficients obtained from the regression analysis with  $R^2$  values ranging from 0.72 to 0.98. The coefficients  $a, b, c, d, e, f$ , and  $g$  are variable with different horizontal cross-section heights within one standard cross-section.

Figure 4.20 represents the arbitrary horizontal cross-sections within a standard CFRD cross-section. It could be noticed that all parameters of different horizontal cross-sections are unique.

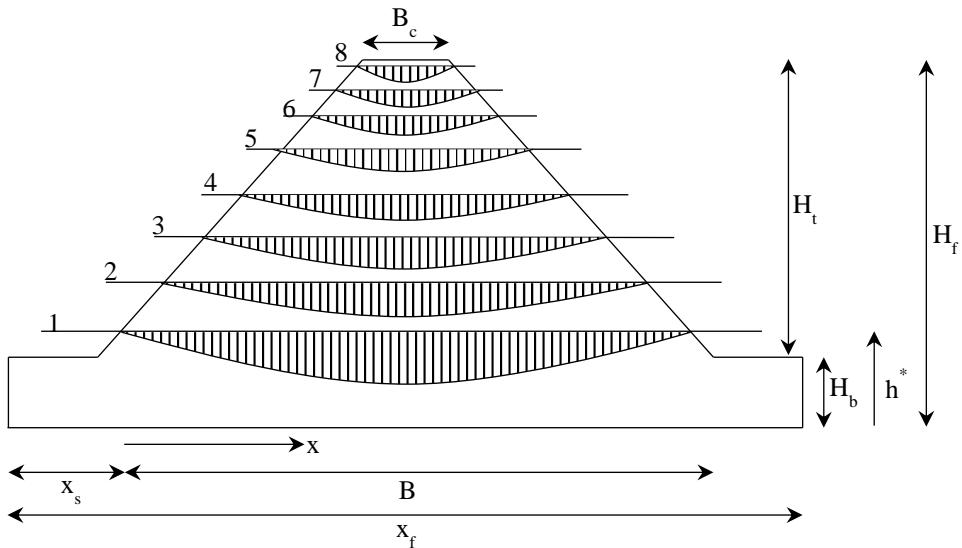

Figure 4.20 Parameters of generalization

In order to search for a possible relationship between the parameters and coefficients, 8 arbitrary horizontal cross-sections were chosen and analysed. Table 4.6. summarizes the raw data obtained from PLAXIS for 40 m-high standard cross-section.

The vertical effective stress distribution data of other cross-sections are presented in Appendix D.

Table 4.6 Vertical effective stresses of arbitrary cross-sections 1 to 4 ( $h^*$ ) of 40-m-high cross-section

$h^* = 10.134 \text{ m}$		$h^* = 14.992 \text{ m}$		$h^* = 20.006 \text{ m}$		$h^* = 25.008 \text{ m}$

The values of  $x$  and  $h^*$  in Table 4.6 and Table 4.7 represent the horizontal and vertical distance measured from the bottom left corner of the cross-section  $(0, 0)$ , respectively. Column for  $\sigma'_v$  is provided for effective stress in kN/m<sup>2</sup> and the (-) sign represents compression. The parameters  $H_f$ ,  $H_t$ , and  $H_b$  are constant in a single standard cross-section, whereas  $h^*$ ,  $B^*$ ,  $x_s$ ,  $x_f$ ,  $\sigma'_{vmax}$ , and  $\sigma'_{vmin}$  are variable between the arbitrary horizontal cross-sections. These parameters are defined as:

$h^*$  : height of the horizontal cross-section from the base of the dam cross-section (See Figure 4.20).

$B^*$  : width of the cross-section at any horizontal layer. Defined as:

$$B^* = (S_u + S_d)(H_f - h^*) + B_c \quad (4.23)$$

$S_d$  : horizontal run for 1 m-rise at downstream side slope

$S_u$  : horizontal run for 1 m-rise at upstream side slope

$B_c$  : width of the crest

$x_s$  : distance of the beginning of the horizontal cross-section from X=0

$x_f$  : distance of the end of the horizontal cross-section from X=0

$\sigma'_{vmax}$  : maximum value of the effective stress of the horizontal layer

$\sigma'_{vmin}$  : minimum value of the effective stress of the horizontal layer

A number of operations were conducted in order to define a dimensionless effective stress distribution. The governing equation was proposed by the functional relationship with reference to the dimensionless plot of the relevant data as shown in Figure 4.21. Legend shows  $h^*$  values of 8 arbitrary horizontal layers.

$$f\left(\frac{2(x - x_s)}{B^*} - 1\right) = \frac{\sigma'_v}{\sigma'_{vmax}} \quad (4.24)$$

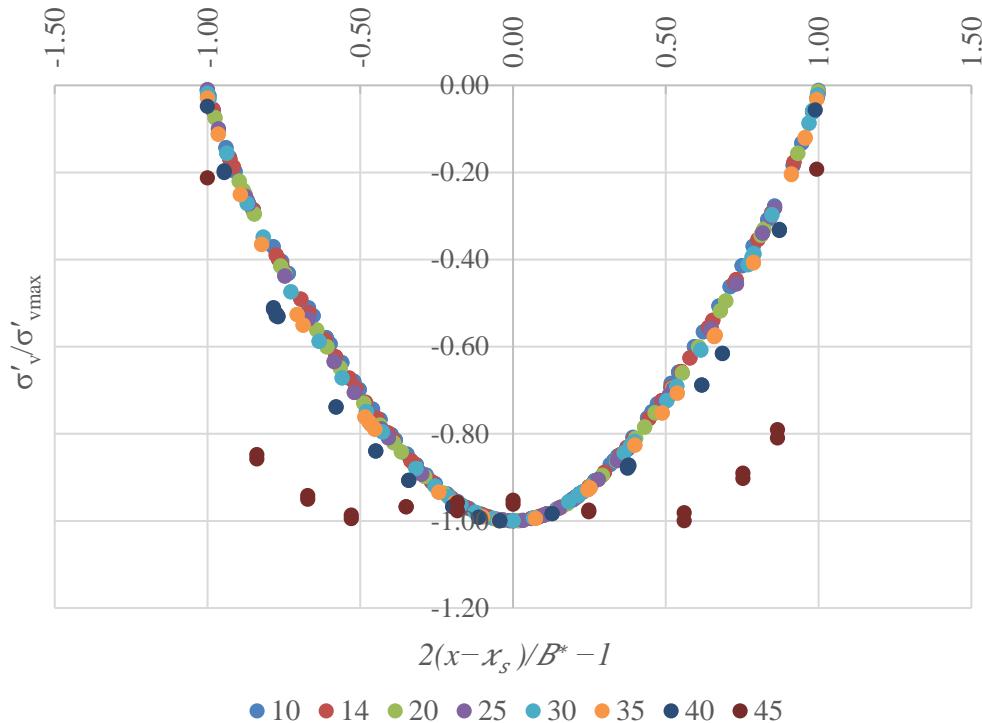

Figure 4.21 Graphical representation of the governing equation for 8 arbitrary horizontal layers of 40 m-high cross-section

As it can be observed from Figure 4.21, the data tend to follow a trend except the levels close to the dam crest elevation. The effective stress distributions of all individual and arbitrary horizontal cross-sections were expressed by a 6<sup>th</sup> degree polynomial with LINEST function of MS EXCEL, which uses the data given in Table 4.8 with the least squares method. In Table 4.8:

$$\alpha = \frac{(h^* - H_b)}{H_f} \quad (4.25)$$

Table 4.8 Coefficients of the effective stress distributions given in Figure 4.22

The true dimensionless effective forces,  $P'_{vt}$ , below the effective stress distributions were defined as:

$$P'_{vt} = \frac{\int_{x_s}^{x_f} \sigma'_v(x) dx}{\sigma'_{vmax} B^*} \quad (4.26)$$

The true dimensionless effective forces,  $P'_{vt}$ , were also analysed and presented in Figure 4.22 with the other parameters. Finally, the procedure was held for all standard cross-sections ranging from 40 m to 200 m heights and the results are summarized in Table 4.9.

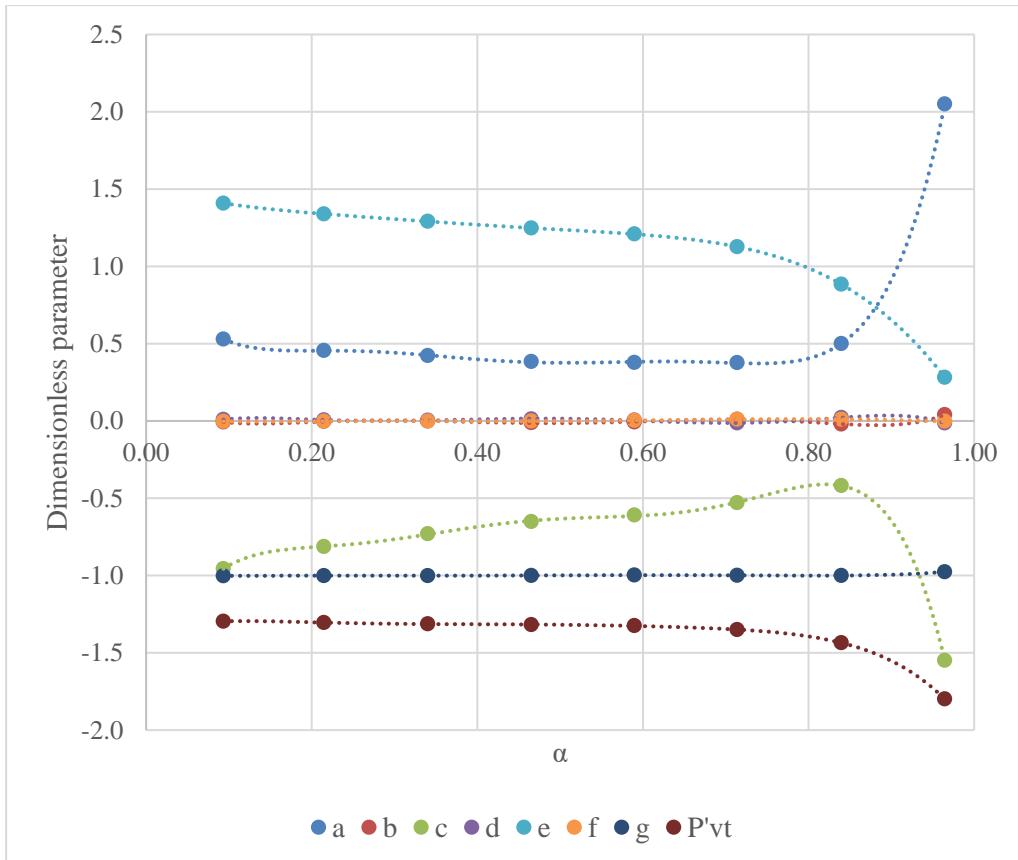

Figure 4.22  $\alpha$  versus parameters  $a$  through  $g$  and true dimensionless effective forces

The graph showing the trend of parameters  $a, b, c, d, e, f$ , and  $g$  is presented in Figure 4.23. Regression analysis was implemented for modelling the parameters as 9-degree polynomials with  $R^2$  values ranging from 0.72 to 0.98. These coefficients and true vertical effective force,  $P'_{vt}$ , are presented as Equations 4.26 to 4.33.

Figure 4.23 Parameters of Eq.4.22 of all cross-sections

$$a = 13215.2\alpha^9 - 53568.49\alpha^8 + 91030.86\alpha^7 - 84270.12\alpha^6 \\ + 46217.74\alpha^5 - 15292.63\alpha^4 + 2973.97\alpha^3 \\ - 313.91\alpha^2 + 14.18\alpha + 0.39 \quad (4.27)$$

$$b = 728\alpha^9 - 3241.33\alpha^8 + 6116.43\alpha^7 - 6361.34\alpha^6 + 3968.09\alpha^5 \\ - 1513.57\alpha^4 + 345.19\alpha^3 - 44.16\alpha^2 + 2.81\alpha - 0.07 \quad (4.28)$$

$$c = -16962.29\alpha^9 + 67907.76\alpha^8 - 113791.92\alpha^7 + 103699.22\alpha^6 \\ - 55875.36\alpha^5 + 18118.17\alpha^4 - 3440.83\alpha^3 \\ + 351.92\alpha^2 - 14.37\alpha - 0.89 \quad (4.29)$$

$$d = -416.55\alpha^9 + 2010.21\alpha^8 - 4064.37\alpha^7 + 4476.63\alpha^6 \\ - 2922.72\alpha^5 + 1153.53\alpha^4 - 269.37\alpha^3 + 34.98\alpha^2 - 2.24\alpha + 0.05 \quad (4.30)$$

$$e = 4097.75\alpha^9 - 15794.47\alpha^8 + 25278.33\alpha^7 \pm 21791.18\alpha^6 \\ + 10967.13\alpha^5 - 3263.44\alpha^4 + 553.42\alpha^3 - 47.54\alpha^2 + 0.70\alpha + 1.47 \quad (4.31)$$

$$f = -232.38\alpha^9 + 918.04\alpha^8 - 1519.17\alpha^7 + 1371.32\alpha^6 - 737.09\alpha^5 \\ + 241.62\alpha^4 - 47.39\alpha^3 + 5.19\alpha^2 - 0.26\alpha + 0.01 \quad (4.32)$$

$$g = 165.05\alpha^9 \pm 732.87\alpha^8 + 1366.68\alpha^7 - 1390.63\alpha^6 + 840.17\alpha^5 \\ - 307.59\alpha^4 + 66.82\alpha^3 - 8.07\alpha^2 + 0.47\alpha - 1.01 \quad (4.33)$$

$$P'_{vt} = 52.78\alpha^9 - 137.57\alpha^8 + 77.63\alpha^7 + 93.81\alpha^6 - 153.32\alpha^5 \\ + 87.14\alpha^4 - 24.04\alpha^3 + 3.25\alpha^2 - 0.29\alpha - 1.29 \quad (4.34)$$

### 4.5.3 Forming the Optimization Algorithm

The optimization for determining the number of stress measuring devices was conducted by the minimization of the total cost of the system,  $C_T$ :

$$C_T = C_E + C_P \quad (4.35)$$

where  $C_E$  and  $C_P$  are the cost of equipment and the cost of penalty, respectively.

Cost of penalty is a measure of how well the pressure distribution is represented by the instrument configuration concerned. As mentioned before, the actual stress distribution is of a high degree polynomial. However, the outputs of an instrumentation system compromise a finite number of sensors connected to each other with straight lines (Figure 4.24).

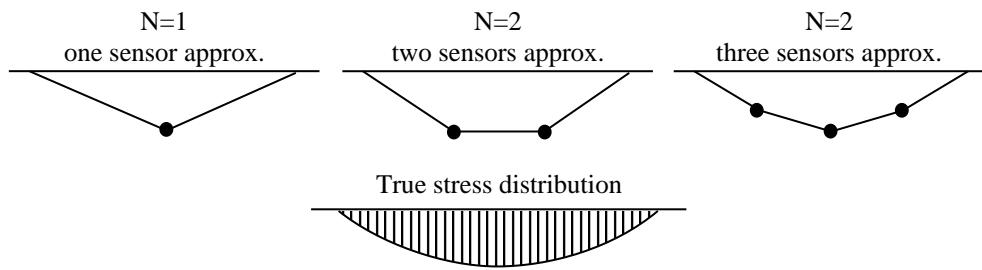

Figure 4.24 Representation of sensor approximations and true stress distribution

Cost of penalty reflects the quality of the information. With the implementation of minimum number of allowable sensors (i.e. one), the cost of the instrumentation system will be lowest which provides poor information about the structural behaviour. On the contrary, with the increasing number of sensors, the cost of the instrumentation system and the quality of the information will increase. Cost of penalty is then defined as the multiplication of the percent difference between the actual area and the computed area under the true effective stress distribution and the linear representation by the instrumentation system, respectively, and the cost difference between the system with maximum and minimum allowed number of sensors.

Cost of equipment is the sum of cost of each sensor  $C_s$  and the cost of cable  $C_c$ . Switchbox is assumed to be located at the downstream face of the dam with the same height of the horizontal layer. The cables are single-core; thus all sensors use their individual cables for connection to the switchbox. The cost of all instruments and the additional equipment used in this study are provided in Appendix A.

The projected vertical effective forces obtained from the different sensor combinations were calculated by the trapezoidal rule. Then the projected vertical effective forces were generalized. Figure 4.24 illustrates the projected vertical effective stress distributions with finite number of instruments and the comparison with the true vertical effective stress distribution. In this figure,  $N$  is the number of instruments.

**$N=1$**

$$P'_v = \frac{B^*}{N + 1}(\sigma'_1) \quad (4.36)$$

$$\sigma'_1 = \sigma'_v \left( \frac{B^*}{N + 1} \right) \quad (4.37)$$

$$C_E = NC_S + N \left( \frac{B^*}{N + 1} \right) C_C \quad (4.38)$$

**$N=2$**

$$P'_v = \frac{B^*}{N + 1}(\sigma'_1 + \sigma'_2) \quad (4.39)$$

$$\sigma'_2 = \sigma'_v \left( \frac{2B^*}{N + 1} \right) \quad (4.40)$$

$$C_E = NC_S + \left( \frac{B^*}{N + 1} \right) (N^2 - 1) C_C \quad (4.41)$$

*N=3*

$$P'_v = \frac{B^*}{N+1}(\sigma'_1 + \sigma'_2 + \sigma'_3) \quad (4.42)$$

$$\sigma'_3 = \sigma'_v \left( \frac{3B^*}{N+1} \right) \quad (4.43)$$

$$C_E = NC_S + \left( \frac{B^*}{N+1} \right) (N^2 - 3) C_C \quad (4.44)$$

*N=4*

$$P'_v = \frac{B^*}{N+1}(\sigma'_1 + \sigma'_2 + \sigma'_3 + \sigma'_4) \quad (4.45)$$

$$\sigma'_4 = \sigma'_v \left( \frac{4B^*}{N+1} \right) \quad (4.46)$$

$$C_E = NC_S + \left( \frac{B^*}{N+1} \right) (N^2 - 6) C_C \quad (4.47)$$

*N=5*

$$P'_v = \frac{B^*}{N+1}(\sigma'_1 + \sigma'_2 + \sigma'_3 + \sigma'_4 + \sigma'_5) \quad (4.48)$$

$$\sigma'_5 = \sigma'_v \left( \frac{5B^*}{N+1} \right) \quad (4.49)$$

$$C_E = NC_S + \left(\frac{B^*}{N+1}\right)(N^2 - 10)C_C \quad (4.50)$$

**N=6**

$$P'_v = \frac{B^*}{N+1}(\sigma'_1 + \sigma'_2 + \sigma'_3 + \sigma'_4 + \sigma'_5 + \sigma'_6) \quad (4.51)$$

$$\sigma'_6 = \sigma'_v \left( \frac{6B^*}{N+1} \right) \quad (4.52)$$

$$C_E = NC_S + \left(\frac{B^*}{N+1}\right)(N^2 - 15)C_C \quad (4.53)$$

The form of the cost of the equipment,  $C_E$ , is then given by:

$$C_E = NC_S + \left(\frac{B^*}{N+1}\right)\left(N^2 - \frac{(N^2 - N)}{2}\right)C_C \quad (4.54)$$

In general form, cost of equipment for various number of instruments,  $N$ , can be expressed by the following function:

$$C_E(N) = N \left( C_S + C_C \frac{B^*}{2} \right) \quad (4.55)$$

The modelled vertical effective force can also be generalized as function below for various number of instruments on a layer:

$$P'_v(N) = \left(\frac{B^*}{N+1}\right) \sum_{i=1}^N \sigma'_v \left( \frac{B^*(i)}{N+1} \right) \quad (4.56)$$

Finally, the objective function can be expressed by:

Minimize

$$C_T = C_E + C_P \quad (4.35)$$

Subject to:

$$N \geq 1 \quad (4.57)$$

$$N \leq B^*/2 \quad (4.58)$$

$$P'_v(N) = \left( \frac{B^*}{N+1} \right) \sum_{i=1}^N \sigma'_v \left( \frac{B^*(i)}{(N+1)} \right) \quad (4.56)$$

$$\sigma'_v(x) = ax^6 + bx^5 + cx^4 + dx^3 + ex^2 + fx + g \quad (4.22)$$

$$C_E(N) = N \left( C_S + C_c \frac{B^*}{2} \right) \quad (4.55)$$

$$C_{Diff} = C_E \left( \frac{B^*}{2} \right) - C_E(1) \quad (4.59)$$

$$Err(N) = \frac{P'_{vt} - P'_v(N)}{P'_{vt}} \quad (4.60)$$

$$C_P(N) = C_{Diff} Err(N) \quad (4.61)$$

where;

$B^*$  : width of a horizontal layer

$P'_v(N)$  : modelled vertical dimensionless effective force function

This objective function can be solved in MS EXCEL environment without any need for complex linear or non-linear solvers. A detailed view of the working spreadsheet is provided in Appendix E.

## 4.6 The Outcomes of the Algorithm

### 4.6.1 Algorithm Outputs

The proposed algorithm was applied to the aforementioned CFRD cross-sections. The third approach was selected for the determination of the number of the horizontal projections to be equipped with sensors. The optimal number of horizontal projections and the number of sensors were computed from the algorithm and the maximum of the ratio of percent error reduction to percent cost increase ( $E\downarrow / C\uparrow$ ) was chosen as an optimum solution.

Table 4.10 provides detailed information about the percent error decreases and cost increases for different number of horizontal projections,  $M$ , of CFRD cross-sections with heights ranging from 40 m to 120 m from thalweg.

#### 4.7 Evaluation of the Consequences of External Effects

Some external interventions, such as seepage and earthquake loading were also analysed. As mentioned before, the readouts of stress measurement sensors can be used for assessing the possibility of increased leakage. The effects of the seepage and the earthquake loading on the sensor configuration will be analysed in the following sections. Evaluation of the alternative sensor placement is also considered in terms of both accurate modelling of stress distribution and cost.

#### 4.7.1 Effect of Seepage

The design principles of CFRDs dictate that the concrete upstream face is watertight during the lifetime of the dam. Moreover, the dam body consists of homogeneous rockfill without any impervious core. The lack of impervious core and its filters makes CFRDs immune to any seepage through the dam body which might occur from possible cracking of the concrete upstream face.

In order to assess the internal effective stress changes within the dam body in case of any possible leakage through the concrete upstream face, a number of analyses were conducted. The plate element was modified to allow water to seep through from different locations, such as at a location at maximum reservoir level (Figure 4.26-b), half (Figure 4.26-c), and one fourth (Figure 4.26-d) of the dam height and the model was rerun. Results of these analyses were compared with no-seepage case (Figure 4.26-a). Sensor locations are also shown in these figures by white dots.

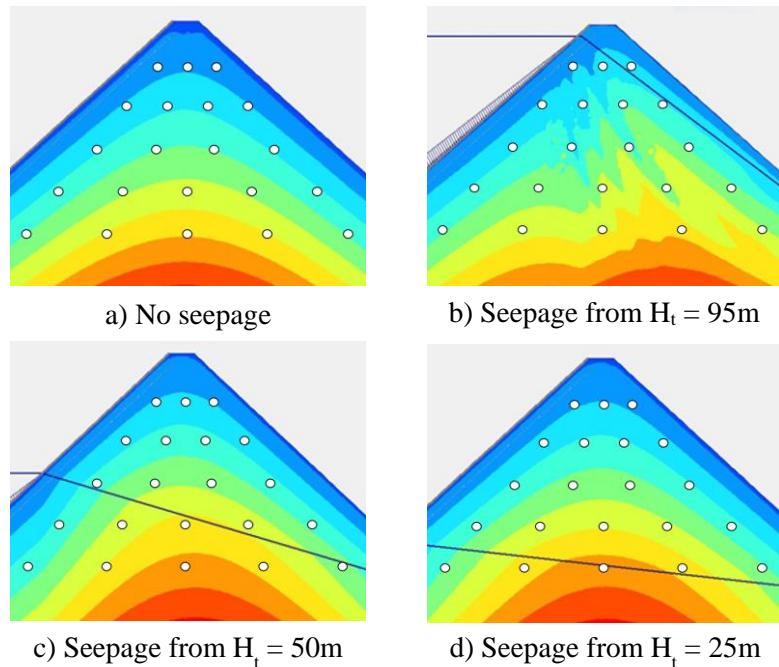

Figure 4.26. Comparison of the internal stresses of four cases

It is observed that the extreme effective stress values were decreased around 30% for case b, described in Figure 4.26 due to pore water pressures induced as a result of cracking. Because of lower crack elevations for cases c and d, the majority of the dam body was not influenced significantly from seepage. The effective stress values were observed to decrease around zones close to the upstream face of the dam.

As a result of this analysis, it can be said that a possible seepage would not create a safety deficiency within the dam body, whereas there may be some significant economic consequences due to the loss of water. It is also believed that the proposed sensor layout is capable of capturing the effective stress decrease caused from a possible seepage. This decrease is to be considered as a warning remark for possible cracking of the upstream face slab. Remedial actions can then be taken with reference to visual observations at the upstream face block and rate of seepage.

#### **4.7.2 Effect of Earthquake**

CFRDs are considered as one of the well-performing dam types during large magnitude earthquakes (ICOLD, 2005) because of the dam fill body being not under the effect of uplift pressure. As a result of this fact, earthquake loading was not taken into account during algorithm building procedures.

For assessing and verifying the assumptions, a dynamic earthquake analysis was conducted to a 100-meter-high cross-section with PLAXIS. A sample data for a strong motion displacement is considered. For this purpose, a strong earthquake occurred in Van, Turkey on 23.10.2011 with a Richter magnitude of 7.2 was analysed. The extreme horizontal displacements of the dam body were compared before and after the earthquake and the residual earthquake displacement after the earthquake was observed to be smaller than 1 cm. This result also proves the resistance ability of the CFRDs against dynamic earthquake loading. In order to trigger the stress/strain measuring sensors and fully assess the real earthquake response of the dam body, it is

advised to use three accelerometers at each dam. Darbre (1995) recommends mounting one accelerometer to the crest of the dam, second one to the foundation of the same cross-section with the first one, and the last one to the close vicinity of the dam body as a free-field accelerometer.

#### 4.8 Effect of Alternative Placement of Sensors

In order to visualize the effect of possible modifications of the height of the horizontal layers, thus the number of the sensors, an arbitrary cross-section was analysed. To this end, 80-meter-high dam was taken into account and several alternative horizontal layers were considered. In the optimal solution, the algorithm output gave 4 horizontal layers with 16 sensors. In the first alternative, only the height of the first horizontal layer was changed. It was shifted to a place 5 m higher than the original height. In the second alternative, all horizontal layers were shifted downwards by 4 m, whereas in the third alternative they were shifted upwards by 4 m.

Table 4.14. Summary of the effect of alternative placement

Case	$h^*$ (m)	Average Error (%)	Cost per sensor (\$)
Optimal Solution	28.8	2.40	1,073.20
	44.8		
	60.8		
	76.8		
First Alternative	33.8	2.56	1,060.08
	44.8		
	60.8		
	76.8		
Second Alternative	24.8	2.18	1,109.27
	40.8		
	56.8		
	72.8		
Third Alternative	32.8	2.57	1,039.60
	48.8		
	64.8		
	80.8		

It can be observed that these changes either lower the average error or the cost per sensor but not both at the same time. It can, therefore, be said that the optimal solution gave the best combination of lowest percent modelling error and lowest cost per instrument. The summary of the effect of alternative placement of the sensors is presented in Table 4.14.

## 4.9 Concluding Remarks

In this chapter, an algorithm for optimal design of stress measuring sensors was developed. The logic behind this algorithm is to find out the best combination of the quality of the information gained and the total cost of the configuration.

This algorithm gives the optimum configuration of a monitoring system consists of total pressure cells and settlement cells, because the stress and the strain is related with each other and these two types of instruments are interchangeable during the design of the instrument system according the specific monitoring interests.

Leakage measuring sensors are omitted from the decision support system because in most of the designs, face slabs are considered as completely impermeable. It is expected that total pressure cells can provide information about an abrupt change in the effective stresses which is an indication of a possible leakage problem from the impervious upstream face slab.

In the following chapter, this algorithm was applied to a number of existing CFRDs around the world and the results of the proposed algorithm were compared with those of the existing cases.

## **CHAPTER 5**

### **APPLICATION OF THE ALGORITHM**

#### **5.1 Introductory Remarks**

The outcomes of this study were compared with the instrumentation layout of a number of existing dams. The existing layouts and the proposed layouts were compared in a number of terms. Only total pressure cells and settlement cells located in the dam body are taken into account while evaluating the existing configurations. Contact pressure cells, settlement cells and strain meters located in and around close vicinity of concrete face slab are not considered in this study.

#### **5.2 Verification and Discussion**

##### **5.2.1 Shuibuya Dam, China**

Shuibuya Dam is 233 m-high from foundation and has a base width of 623 m. In the existing configuration, 38 strain measuring sensors (settlement cells) were installed on five horizontal projections along with other types of instruments (Wei et al., 2010). The locations of the aforementioned sensors are shown in Figure 5.1 (dimensions are in meters).

The proposed algorithm was run with the dimensions of Shuibuya Dam and a six-horizontal layer configuration was obtained.

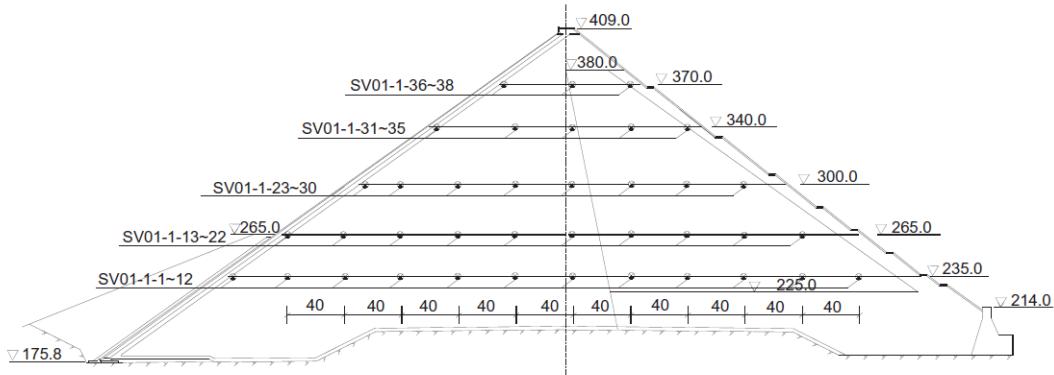

Figure 5.1 Shuibuya Dam settlement cell locations (Wei et al, 2010)

In the existing case, Shuibuya Dam has a total of 38 strain (settlement) measuring sensors on 5 horizontal layers. However, the algorithm recommended that a similar dam cross-section should be equipped with 35 sensors on 6 horizontal projections. Cost of the existing configuration was also evaluated in Table 5.1 with the assumption of switchboxes being provided at the downstream of the dam for each layer and the sensors use their own single-core cables.

Table 5.1 Comparison of existing and proposed configurations of  
Shuibuya Dam

Existing Configuration				Proposed Configuration			
Layer	h* (m)	N	COST (\$)	Layer	h* (m)	N	COST (\$)
1	59.2	12		1	60.8	7	
2	89.2	10		2	89.5	7	
3	124.2	8		3	118.2	6	
4	164.2	5		4	146.9	6	
5	194.2	3		5	175.6	5	
TOTAL				6	204.3	4	
TOTAL		38	65,062.64	TOTAL		35	56,977.59

It can be observed that the proposed configuration has not only lower total cost compared to the existing configuration but also provides lower cost per instrument as \$1628 compared to the \$1712 of existing configuration. The location of the first two horizontal projections are very close to each other for both configurations. However, the advantage of the proposed configuration can be identified when the information gained from sensors with the inclusion of an additional horizontal layer is considered.

### **5.2.2 Tanyeri Dam, Turkey**

Tanyeri Dam is a 100 m-high CFRD from thalweg. It is one of the dams of Fatsa projects and located in the Eastern Black Sea Region of Turkey. The maximum reservoir level is 98 m. Upstream face slope is 1V:1.41H, whereas the downstream slope is 1V:1.4H.

The dam body was designed with a contemporary approach as zoned fill. At the mid-axis, the dam body is equipped with 11 total pressure cells and 11 settlement cells, a total number of 22 stress and strain (settlement) monitoring sensors. Each total pressure cell is installed along with a settlement cell in 3 horizontal levels.

The proposed algorithm was run with the dimensions of Tanyeri Dam and a five-horizontal layer configuration was obtained. The algorithm recommended that a similar dam cross-section should be equipped with 21 sensors on 5 horizontal projections. The comparison and the cost of the existing and proposed configuration is presented in Table 5.2.

Table 5.2 Comparison of existing and proposed configurations of Tanyeri Dam

Existing Configuration				Proposed Configuration			
Layer	h* (m)	N	COST (\$)	Layer	h* (m)	N	COST (\$)
1	46.0	10		1	32.7	5	
2	89.2	6		2	49.3	5	
3	124.2	6		3	66.0	4	
				4	82.7	4	
				5	99.3	3	
TOTAL	22	24,492.51		TOTAL	21	24,472.00	

It can be observed that the cost and the number of instruments are nearly identical between the existing and proposed configurations. However, because of having more horizontal layers, it is obvious that the proposed algorithm will provide a better picture of the overall stress behaviour within the dam body.

### 5.2.3 Zipingpu Dam, China

Zipingpu Dam is a 134 m-high CFRD from thalweg and located 60 km northwest of Chengdu of Sichuan Province (Xu et al., 2012). The height from foundation is 156 m and the ratio between  $H_f$  and  $H_t$  is 1.16 which is fully compatible with the assumption of this study. The crest width is 12 m and the maximum reservoir level is 127 m. The upstream face slope is 1V:1.4H, whereas the downstream slope is 1V:1.5H.

At the mid-axis, the dam body is equipped with 30 settlement cells, installed in 4 horizontal levels. All settlement cells are also mated with horizontal displacement meters.

The proposed algorithm was run with the dimensions of Zipingpu Dam and a six-horizontal layer configuration was obtained. The algorithm recommended that a similar dam cross-section should be equipped with 29 sensors on 6 horizontal projections. The comparison and the cost of the existing and proposed configuration is presented in Table 5.3.

Table 5.3 Comparison of existing and proposed configurations of  
Zipingpu Dam

Existing Configuration				Proposed Configuration			
Layer	h* (m)	N	COST (\$)	Layer	h* (m)	N	COST (\$)
1	32.0	10		1	40.7	6	
2	68.0	9		2	59.9	6	
3	92.0	7		3	79.2	5	
4	122.0	4		4	98.4	5	
				5	117.6	4	
				6	136.8	3	
TOTAL		30	45,176.80	TOTAL		29	38,724.80

It can be observed that the number of instruments are very close in the existing and proposed configurations. However, because of having fewer horizontal layers, the cost of the existing configuration is more than the cost of the proposed configuration. This is an expected result because of the dominance of the cost of the cable.

As a summary, it can be said that the result of the algorithm decreases the cost of the instrumentation system while maintaining the accuracy of the modelling of stress behaviour within the dam body.

### 5.2.4 Tianshengqiao-I Dam, China

Tianshengqiao-I Dam is a 176 m-high CFRD from foundation and located on the Nanpan river. At the maximum cross-section, the dam body is equipped with 16 settlement cells for vertical strain (settlement) monitoring. Vertical displacement sensors are placed in 4 horizontal levels.

The proposed algorithm was run with the dimensions of Tianshengqiao-I Dam and a six-horizontal layer configuration was obtained. The algorithm recommended that a similar dam cross-section should be equipped with 32 sensors on 6 horizontal projections. The comparison and the cost of the existing and proposed configuration is presented in Table 5.4.

Table 5.4 Comparison of existing and proposed configurations of Tianshengqiao-I Dam

Existing Configuration				Proposed Configuration			
Layer	h* (m)	N	COST (\$)	Layer	h* (m)	N	COST (\$)
1	50.0	1		1	46.0	7	
2	77.0	6		2	67.7	6	
3	110.0	6		3	89.5	6	
4	143.0	3		4	111.2	5	
				5	132.9	4	
				6	154.6	4	
TOTAL	16	23,594.00		TOTAL	32	45,219.20	

The existing configuration of the Tianshengqiao-I Dam comprises considerably less amount of sensors compared to the proposed configuration. A high CFRD, such as Tianshengqiao-I Dam should have been monitored in more detail. However, this result might also be related with the sensor availability and the unit prices of the sensors

during the era when the dam is constructed (between 1992-1998). It can be easily said that the proposed algorithm will provide a much better visualization of the overall stress behaviour within the dam body.

### **5.2.5 Berg River Dam, South Africa**

Berg River Dam is a 67 m-high dam on the Berg River. It was constructed between 2004 and 2009. The existing configuration consists of 12 sensors located on 3 layers. The first layer has 6 sensors, the second one has 4 sensors, and the last one has 2 sensors.

The proposed algorithm was executed with the dimensions of Berg River Dam and a three-horizontal layer configuration was obtained. The algorithm recommended that a similar dam cross-section should be equipped with 11 sensors on 3 horizontal projections. The proposed configuration can be considered as similar to the existing case.

### **5.2.6 Kürtün Dam, Turkey**

Kürtün Dam is a 133 m-high dam from foundation. It is located on the Harşit River. The existing configuration, excluding the contact pressure cells at the face slab, comprises 7 total pressure cells and 12 settlement cells on 4 layers.

The comparison of the existing and proposed configurations is presented in Table 5.5. The proposed algorithm output for a dam with similar dimensions consist of 22 sensors for stress monitoring on 5 horizontal projections. The algorithm recommends 3 more sensors in a symmetrical placement. The cost of existing and proposed configurations are very close to each other.

Table 5.5 Comparison of existing and proposed configurations of Kürtün Dam

Existing Configuration				Proposed Configuration			
Layer	h* (m)	N	COST (\$)	Layer	h* (m)	N	COST (\$)
1	38.0	7		1	41.3	6	
2	58.0	7		2	59.7	5	
3	83.0	4		3	78.0	4	
4	108.0	1		4	96.3	4	
				5	114.7	3	
TOTAL	19	25,407.28		TOTAL	22	25,908.08	

### 5.2.7 Nam Ngum 2 Dam, Laos

Nam Ngum 2 Dam is a 181 m-high dam from foundation. The construction was completed on 2011. It is located on the Nam Ngum River. The existing configuration consists of 14 sensors located on 3 layers. The first layer has 3 sensors, second one has 6, and the last one has 5 sensors.

Table 5.6 Comparison of existing and proposed configurations of Nam Ngum 2 Dam

Existing Configuration				Proposed Configuration			
Layer	h* (m)	N	COST (\$)	Layer	h* (m)	N	COST (\$)
1	7.0	3		1	37.9	7	
2	59.0	6		2	61.7	7	
3	119.0	5		3	85.6	6	
				4	109.4	5	
TOTAL	14	20,441.40		5	133.3	5	
				6	157.1	4	
				TOTAL	34	53,892.83	

The proposed algorithm was executed with the dimensions of Nam Ngum 2 Dam and a six-horizontal layer configuration was obtained. The algorithm recommended that a similar dam cross-section should be equipped with 34 sensors. It can be said that Nam Ngum 2 Dam is under-instrumented comparing with the other CFRDs. The comparison of the existing and proposed configurations is presented in Table 5.6.

### **5.2.8 Cethana Dam, Australia**

Cethana Dam is a 110 m-high dam from foundation. It is located on the Forth River at north-western Tasmania. The construction was completed on 1971. The existing configuration comprises 4 total pressure cells on 2 layers. Comparison of the existing and proposed configurations is presented in Table 5.7.

Table 5.7 Comparison of existing and proposed configurations of Cethana Dam

Existing Configuration				Proposed Configuration			
Layer	h* (m)	N	COST (\$)	Layer	h* (m)	N	COST (\$)
1	25.0	2		1	31	5	
2	50.0	2		2	46.8	5	
				3	62.6	4	
				4	78.4	4	
				5	94.2	3	
TOTAL		4	5,216.70	TOTAL		21	40,149.66

The proposed algorithm output for a dam with similar dimensions consist of 21 sensors for stress monitoring on 5 horizontal projections. Because of being a relatively old dam, Cethana Dam is under-instrumented when compared to the more recent designs.

## **5.2.9 Salvajina Dam, Colombia**

Salvajina Dam is a 148 m-high dam from foundation. The construction was completed on 1985. It is located on the Cauca River. The existing configuration consists of 25 sensors located on 6 layers.

The proposed algorithm was executed with the dimensions of Salvajina Dam and a six-horizontal layer configuration was obtained. The algorithm recommended that a similar dam cross-section should be equipped with 29 sensors. The number of sensors are close to each other in both configurations. The comparison of the existing and proposed configurations is presented in Table 5.8.

Table 5.8 Comparison of existing and proposed configurations of Salvajina Dam

Existing Configuration				Proposed Configuration			
Layer	h* (m)	N	COST (\$)	Layer	h* (m)	N	COST (\$)
1	31.0	3		1	38.29	6	
2	47.0	8		2	56.57	6	
3	61.0	3		3	74.86	5	
4	80.0	6		4	93.14	5	
5	94.0	1		5	111.43	4	
6	110.0	4		6	129.71	3	
TOTAL		25	29,591.41	TOTAL		29	37,968.13

## **5.2.10 Xingó Dam, Brazil**

Xingó Dam is a 150 m-high dam from foundation. It is located on the São Francisco River. The construction was completed on 1994. The existing configuration comprises 12 sensors on 3 layers.

The proposed algorithm was executed with the dimensions of Xingó Dam and a six-horizontal layer configuration was obtained. The algorithm recommended that a similar dam cross-section should be equipped with 33 sensors. The comparison of the existing and proposed configurations is presented in Table 5.9. It can be said that Xingó Dam is under-instrumented according to the algorithm results.

Table 5.9 Comparison of existing and proposed configurations of Xingó Dam

Existing Configuration				Proposed Configuration			
Layer	h* (m)	N	COST (\$)	Layer	h* (m)	N	COST (\$)
1	55	5		1	29.1	7	
2	85	4		2	49.3	6	
3	110	3		3	69.4	6	
				4	89.6	5	
				5	109.7	5	
				6	129.9	4	
TOTAL		12	13,430.40	TOTAL		33	48,404.83

### 5.3 Comparison of the Results

The outputs of the algorithm have already been compared with the existing configurations. Results of the comparisons are outlined in Table 5.10 together with the results obtained from Eqns. 3.1 and 3.2.

The total number of sensor outputs of the proposed configuration and the results of the preliminary equation were observed to give close results for the dam heights,  $H_t$ , higher than 100 m. However, the preliminary information obtained from Eqns. 3.1 and 3.2 tends to propose fewer sensors for the dam heights,  $H_t$ , lower than 100 m.

Table 5.10 Comparison of different configurations

Dam	$H_f$ (m)	M (Eqn. 3.1)	N <sub>T</sub> (Eqn. 3.2)	Existing		Proposed		
				M	N <sub>T</sub>	M	N <sub>T</sub>	e (%)
Shuibuya	233	5	37	5	38	6	35	1.38
Tanyeri	103.5	3	13	3	22	5	21	0.15
Zipingpu	156	4	23	4	30	6	29	0.79
Tianshengqiau-I	176	4	27	4	16	6	32	0.99
Berg River	67	3	6	3	12	3	11	0.24
Kürtün	133	4	18	4	21	5	21	0.68
Nam Ngum 2	181	4	22	3	14	6	34	0.97
Cethana	110	3	11	2	4	5	21	0.27
Salvajina	148	4	17	6	25	6	29	0.70
Xingó	150	4	17	3	12	6	33	0.66

A more realistic comparison could have been made if the errors of both existing and proposed configurations were considered. However, in most of the existing configurations, the sensors are not placed according to the symmetrical arrangement on a particular horizontal layer as proposed in this study. Since the developed algorithm is only capable of assessing the error of the aforementioned placement within a dam cross-section, the errors for the existing configurations were not computed.

## **CHAPTER 6**

### **CONCLUSIONS**

#### **6.1 Conclusions**

There is not a widely accepted rule set for placement of the sensors within a dam body. The current applications are generally influenced from the past practices and expert judgments. This gap in the related literature enforced the current study to develop an algorithm for optimal design of a stress/strain monitoring system for a CFRD. With this motivation, an algorithm for optimal design of stress monitoring system of a CFRD was developed. This algorithm can be used as a decision support tool during the design of the configuration of the stress measuring sensors of the instrumentation system.

A number of assumptions were made throughout the course of this study. The dam body is assumed as a homogeneous fill with having symmetrical side slopes of 1V:1.5H and a constant freeboard. The rockfill was modelled with the hardening soil model.

The software PLAXIS was executed for various dam heights,  $H_t$ , from 40 m to 200 m with 20 m-increments to obtain effective stress distribution throughout the dam body. The relation between the dam height  $H_f$  and  $H_t$  was obtained using the geometric characteristics of existing rockfill dams of Turkey.

Study of vertical projection of the effective stress distribution at the mid-axis of the dam body provided a mean for determining the number of horizontal layers to be equipped with sensors within the dam body. Three different approaches were considered in the developmental stage of the algorithm and the third approach was chosen to be employed in the algorithm development process with respect to lowest error involved in the modelling.

Effective stress distribution on any horizontal projection was modelled with a six-degree polynomial (Eqn. 4.22). The numerical terms of the aforementioned polynomial were defined as a nine-degree polynomial of the geometrical features of the CFRD cross-section.

The optimization algorithm was formed by the minimization of the sum of cost of equipment and cost of penalty. Cost of penalty was defined as a measure of how well the pressure distribution is represented by the instrument configuration concerned. The actual stress distribution is of a high degree polynomial. However, the output of an instrumentation system compromise a finite number of sensors connected to each other with straight lines. Cost of penalty was defined as the multiplication of the percent difference between the true vertical effective force and the modelled vertical effective force by the instrumentation system and the cost difference between the system with maximum and minimum allowed number of sensors.

In this algorithm, the cost of the instrumentation system and the error that will result from the modelling of true stress distribution as a piece-wise linear distribution is considered. The outcomes of this could provide a basis for number of sensors and their locations in the design stage of instrumentation system of CFRDs ranging from 40 m to 200 m. The results of the proposed configurations are given in Table 4.13.

Effect of seepage and earthquake loading were evaluated. It was observed that the proposed sensor layout is capable of capturing the effective stress decrease caused from a possible seepage. The extreme horizontal displacements of the dam body induced by earthquake effects were compared before and after the earthquake cases and it was observed that the residual earthquake displacement after the earthquake was smaller than 1 cm. Effect of alternative placement of sensors was also studied and it was concluded that the optimal solution gave the best placement combination having lowest percent modelling error and lowest cost per instrument.

The use of the proposed model was tested by applying it to a number of existing dams. The algorithm generally recommended more horizontal projections for a dam body with similar dimensions. The outputs of the algorithm were also observed to give less cost compared to the existing cases.

It is believed that this algorithm would provide a basis for the future enhancements and the further developments would make it a universally accepted practice which can be employed quickly and easily.

## 6.2 Recommendations for Future Studies

In a possible future research, the proposed algorithm can be enriched with the inclusion of other types of instruments, such as piezometers for placing in foundation and body fill. Placement of the strain meters and joint meters to the face slab could be a subject of another optimization study. Some parameters were kept constant during the development of this algorithm, such as crest width, upstream and downstream side slopes, freeboard, and material properties. The effect of the variation of these parameters on the algorithm results may also be studied in order to determine whether they have a significant effect on the placement of the sensors or not.

A similar procedure can also be developed for concrete type of dams. Concrete dams are more sensitive to the changes at stress levels because of being slenderer structures compared to the embankment dams. Since concrete is a more homogeneous material than embankment fill material, the assumptions related with the material properties could be eliminated during the development of the algorithm.

## **APPENDIX A**

In Table A.1 the complete price list of all instruments mentioned in this study are given in U.S. Dollars (USD, \$) with reference to IIC (2007).

Table A.1 Unit prices of instruments

<b>Equipment Type</b>	<b>Unit price per item (\$)</b>
VW Pressure Cell	670.00
VW Piezometer	455.00
V-Notch Weir and Automatic VW Readout Unit	2440.00
Automatic VW Weir Readout Unit	2,177.00
Parshall Flume and Automatic VW Readout Unit	2,672.00
Surface Mount VW Joint meter	625.00
Accelerometer	12,795.00
Common Triggering Unit and Data Recorder for Accelerometers	27,047.00
Surface Mount Clinometer (Tiltmeter)	1,020.00
Instrument Cable	5.60 per meter
Cable Carrier Tray	30.00 per meter
Multiplexer	5,031.00
Data Logger	17,173.00
Software	18,533.00
Handheld Data Readout	6,398.00

## APPENDIX B

Table B.1  $H_f$  and  $H_t$  values of the rockfill dams in Turkey (DSİ, 2012)

Name of the Dam	$H_f$ (m)	$H_t$ (m)
Hirfanlı	83.0	78.0
Sille	40.0	39.0
Mamasin	48.4	44.9
Altınapa	31.5	30.5
Devegeçidi	34.8	32.8
Hasanlar	72.8	70.8
Keban	207.0	163.0
Balçova	73.4	63.4
Hasan Uğurlu	175.0	135.0
Bozkır	52.1	47.1
Suat Uğurlu	51.0	38.0
Doğancı	82.0	64.0
Alaca	57.0	44.3
Belpınar	61.2	58.2
Çamlıdere	106.2	101.7
Germeçtepe	49.0	41.5
Kalecik	80.0	77.0
Kozlu	61.3	60.2
Gödet	93.0	64.0
Kestel	65.0	62.5
Altınkaya	195.0	140.0
Geyik	41.0	39.0
Gökçe	61.0	50.0
Hacıhıdır	38.6	32.0
Kılıçkaya	134.0	103.0
Menzelet	156.5	136.5
Adığüzel	145.0	144.0
Derbent	33.0	29.0
Atatürk	169.0	166.0
Murtaza	41.0	38.0

Table B.1 (continued)

<b>Name of the Dam</b>	<b>H<sub>f</sub> (m)</b>	<b>H<sub>t</sub> (m)</b>
Beyler	40.0	31.0
Çatak	35.0	33.0
Kızılçapınar	60.3	54.3
Kuzgun	120.0	114.0
Tahtalı	57.5	54.5
Sazlıdere	47.0	23.0
Madra	106.0	86.0
Armağan	60.5	57.5
Özluce	144.0	124.0
Yayladağ	47.4	44.4
Sıddıklı	53.0	50.2
Bakacak	60.0	48.0
Sorgun	45.0	33.5
Birecik (1)	63.5	53.5
Kızıldamlar	46.7	40.0
Kürtün	133.0	110.0
Bahçelik	63.5	53.0

## APPENDIX C

Table C.1 Horizontal effective stresses of 40-m-high cross-section

<b>x (m)</b>	<b>y (m)</b>	<b><math>\sigma'_h</math> (kN/m<sup>2</sup>)</b>
98.00	46.40	-2.88
98.00	44.63	-28.14
98.00	44.63	-28.27
98.00	41.93	-65.38
98.00	41.93	-65.37
98.00	39.18	-101.38
98.00	39.18	-101.39
98.00	37.09	-127.91
98.00	37.09	-127.92
98.00	33.54	-172.11
98.00	33.54	-172.10
98.00	32.24	-188.05
98.00	32.24	-188.05
98.00	30.53	-209.40
98.00	30.53	-209.39
98.00	28.29	-237.14
98.00	28.29	-237.15
98.00	26.66	-257.91
98.00	26.66	-257.88
98.00	25.38	-274.24
98.00	25.38	-274.28
98.00	23.17	-303.14
98.00	23.17	-303.14
98.00	21.92	-319.81
98.00	21.92	-319.79
98.00	19.18	-357.74
98.00	19.18	-357.76
98.00	17.35	-383.85
98.00	17.35	-383.89
98.00	16.53	-395.77

Table C.1 (continued)

<b>x (m)</b>	<b>y (m)</b>	<b><math>\sigma'_h</math> (kN/m<sup>2</sup>)</b>
98.00	16.53	-395.72

# **CURRICULUM VITAE**

## **PERSONAL INFORMATION**

Surname, Name: Ari, Onur  
Nationality: Turkish (TC)  
Date and Place of Birth: 1 April 1983, Ankara  
Marital Status: Single  
Phone: +90 312 498 20 68  
Email: onur.ari@me.com

## **EDUCATION**

<b>Degree</b>	<b>Institution</b>	<b>Year of Graduation</b>
MS	QMUL Sustainable Energy Systems	2014
MS	METU Civil Engineering	2008
BS	METU Civil Engineering	2006
High School	Ankara Ataturk Anadolu High School	2001

## **WORK EXPERIENCE**

<b>Year</b>	<b>Place</b>	<b>Enrolment</b>
2015-Present	EnerjiSA	Optimization Specialist
2011-2015	Development Bank of Turkey	Junior Specialist
2006-2011	METU Dept. of Civil Engineering	Research Assistant

## **FOREIGN LANGUAGES**

Advanced English, Intermediate German and French
